Introduction

The retrospective analysis of economic development in this paper refers to the following two periods. The first period is from 1970 through to 1990 during which the republics of the former Union of Soviet Socialist Republics (USSR) operated as centrally planned economies (CPEs). The second period began in 1992 and continues until the present day. During this period, the republics of the former USSR obtained their political independence and entered into a new regional organization called the Commonwealth of Independent States (CIS). At the beginning of the 1990s, the CIS member countries initiated economic reforms intended to transform their CPEs into market-oriented economies. Analysis of the economic performance of these countries during these periods may then not only reveal economic characteristics exclusive to each period, but also some common features. These include the impact of economic reform on changes in their economic structure, rates of economic growth, the standard of living, and other indicators of economic development.

We should note from the outset that comparative analysis of economic performance of these countries presents a considerable problem for a number of reasons. First, the countries operated in a completely new economic environment; economic reforms initiated at the beginning of the 1990s resulted in substantial institutional changes and new forms of economic organization. Second, peculiarities in macroeconomic statistics available for the analysis of economic development make direct comparison difficult. Nevertheless, the comparison of at least some characteristics appears possible. Although the concept of economic production in the material product system (MPS) excludes non-material services, as demonstrated by A. Bergson, its impact on the comparability of rates of economic growth based on either the MPS or the system of national accounts (SNA) is relatively small.

In fact, the comparative rates of net material product (NMP) and gross domestic product (GDP) for any period depend on i) the relative rates of growth of material goods and nonmaterial services, and ii) changes in the share of nonmaterial services used as intermediate inputs for the production of material goods. If i) and ii) do not change over time, the rates of NMP and GDP will lie very close to each other. Finally, we should note that it is not feasible in this paper to embrace all aspects of socioeconomic development in the context of a retrospective analysis. Therefore, the analysis focuses on changes in the most important macroeconomic variables, including GDP and the structure of GDP, output indicators of key industries, investment, inflation, and external trade.

The paper comprises the following parts. Part I provides a discussion of the limitations of the statistical data needed for retrospective analysis (by Y. Ivanov). Part II reviews the economic

development of the republics of the former USSR during 1971–1990 (by T. Khomenko). Part III discusses the economic development of the CIS countries during 1991–2008 (by Y. Ivanov). The authors would like to express their gratitude to V. Akchibash, L. Antsiferova and I. Kostenich for assistance in the preparation of the statistical tables in the text and annexes of the paper.

I. Limitations of a retrospective analysis of the economic performance of republics of the former USSR

The analysis of the economic performance of the republics of the former USSR is largely based on data compiled based on the balance of national economy, known in Western countries and in United Nations (UN) documents as the MPS. Importantly, there was official recognition of the MPS as an alternative system of national accounting to the SNA, and UN statistical publications included figures on the net material product of the USSR submitted by its statistical office.

The underlying concepts, definitions, and classifications of the MPS differ considerably from those in the SNA, and therefore the figures on national product, its structure and the rates of economic growth computed in the two national accounting systems are not directly comparable. Figures on the national product of the USSR used by the UN for assessment of the scale of country contributions to its budget were obtained with the help of a conversion key. This key described the specific adjustments needed to convert net material product (national income using the terminology of the balance of national economy) to the national product, as defined in the SNA. The first attempts to obtain official figures of gross national product in the USSR at the end of the 1980s were with the help of a conversion key that was very similar to that used by the UN Committee of Contributions for the UN budget.

Some other factors also influenced the international comparability of net material product and the rates of economic growth. Some are associated with the system of prices established by the government in the USSR and its republics. There were two distinct levels of prices: relatively low prices on the means of production, which largely excluded turnover tax, and relatively high prices on consumer goods, including turnover tax. This imbalance had two main purposes. First, the relatively low (subsidized) prices of the means of production were to stimulate their use in production and to encourage technical progress. Second, the high prices of consumer goods were to facilitate the collection of taxes for the state budget and to keep the purchases of consumer goods by the population within established limits. This dual-pricing system affected the industrial structure of net material product, the disposition of net material product on final

consumption and capital formation, the weights of individual products, and accordingly, the rate of economic growth.

The Soviet economist V. Belkin, in his volume “Prices of the Unified Level and Economic Measurements on their Basis” released in 1962 by the publisher “Statistica”, undertook analysis of the distortions arising from the dual pricing of some economic variables. In this work, Belkin presented the results of his recalculation of the USSR input–output table for 1959 carried out with the help of a system of equations. This made it possible to distribute profits and turnover tax more evenly between the different groupings of material goods and to obtain a consistent picture of the economy valued at imputed prices at a unified level. For example, in one of his recalculated input–output tables, he distributed profits and turnover tax proportionally to the capital available across the various industries. The data from his experimental calculations revealed enormous differences in the structure of the economy when compared with the structure reflected in actual prices. These differences referred to both the industrial structure of the economy and the ratio between consumption and capital formation. Particularly large differences arose between the shares of agriculture in actual and recalculated prices because the procurement prices paid by the government to agricultural producers were very low and producers often incurred considerable losses. The distinguished American economist, A. Bergson, also attempted to measure the economic performance of the USSR with the help of so-called adjusted factor cost derived by the equal distribution of profits and turnover tax among various products. The Central Intelligence Agency (CIA) used this concept of adjusted factor cost to arrive, from their viewpoint, at a more meaningful estimate of economic growth in the USSR by eliminating the distortions in the existing price system.

Another factor that influenced the reliability and comparability of the rates of economic growth is associated with the faulty price deflators used to obtain net material product in constant prices. The methodology used in the official price statistics of the USSR and its republics was inconsistent with international standards, and used a price list rather than the observation of actual prices in stores. Further, the official price statistics did not take into account the deterioration of the physical characteristics of many commodities. There was also a widespread practice where enterprises in their reports submitted to the statistical offices of the USSR and its republics used current prices (as a substitute for constant prices) in respect of some modification of products not produced in the base year. As a result, there was likely an upward bias in the volume index of industrial output because current prices reflected not only improvements in quality, but also an element of inflation. The official methodology for compiling the MPS also did not contain any provisions for the measurement of the underground economy, even though it existed in reality. Therefore, the official figures on net material product did not contain any of

the necessary adjustments. In contrast, there were cases of the artificial inflating of reports in order to obtain bonuses.

Starting in 1962, the republics of the USSR began compilation of the elements of the MPS and calculated net material product. However, reconciliation of the values of net material product computed by the statistical offices of the USSR and the republics was rather complex because the so-called centralized element of the economy was artificially and arbitrarily assigned, mostly to the Russian Federation. This resulted in some distortions of figures, and created problems in achieving consistency between the various types of economic statistics, and for analysis of the data. One of the peculiarities in the compilation of net material product referred to the treatment of exports and imports and earnings from external trade. This was associated with the different level of prices for exported and imported goods as well as the artificial exchange rate.

According to the procedure used, the balance of exports and imports, originally valued in domestic prices with the conversion of actual external trade prices using the official exchange rate, was adjusted to obtain the valuation of exports and imports in actual domestic prices. The ratio of the value of imports in domestic prices and imports in external trade prices served as an adjustment factor. The resulting net exports were then an element in the disposition of net material product, and the difference between the balance of exports and imports in domestic prices and net exports (called “earnings from external trade”) was added to net material product. However, this was as a whole, and the value-added of individual industries was unaffected¹. This procedure was inconsistent with the methods adopted in the SNA, and so the distribution of earnings from external trade among the republics was very arbitrary.

¹ To clarify this method, consider a simple example. Assume that exports of country A in domestic prices are equal to 100, while imports are equal to 180. Also assume that exports in external trade prices converted to domestic currency with the help of the official exchange rate is equal to 120, while imports in external trade prices converted to domestic currency with the help of the official exchange rate is equal to 130. According to the procedure used in the MPS, net imports was calculated by multiplying net imports in external trade prices, originally converted in domestic currency ($130 - 120 = 10$), by the ratio of imports in domestic prices and imports in external trade prices converted in domestic prices with the official exchange rate. In other words, net imports were as follows: $10 \times 180 / 130 = 14$. Then, the difference between the balance of imports and exports in domestic prices ($180 - 100$) was reduced by net imports computed as above (14). The residual, $80 - 14 = 66$, was added to net material product. This element can be interpreted as the output of external trade. However, if we used the SNA methodology, net imports would be equal to 10 ($130 - 120$) and the output of external trade would be as follows: output in connection with export transactions would be equal to $120 - 100 = 20$ and output in connection with import transactions would be equal to $180 - 130 = 50$. Then, the total output of external trade would be equal to $20 + 50 = 70$. These calculations can also be presented in the following manner:

	MPS	SNA
Production	100	100
Output of external trade	66	70
Net imports	14	10
Total resources	180	180
Final use	180	180

Problems with the analysis of economic performance in CIS countries, 1992–2008

The transformation of the CPE into market economies also required the transformation of their statistics in accordance with international standards. The key SNA 1993 accounts became regular statistical practice because of work undertaken by the statistical offices of the CIS countries. These accounts made it possible to compute GDP using three methods, and to obtain a number of other indicators essential for analysis of the structure of the economy, major components of the final disposition of GDP, and indicators of the income and consumption of households, etc. Unfortunately, compilation of the SNA requires the solution of numerous methodological and practical problems associated with the collection of primary data. Some of these problems continue to remain unsolved. One of these refers to the measurements of the non-observed economy (underground and informal activity). The development of market mechanisms stimulated the rapid growth of these activities, and therefore it was necessary to organize appropriate sources of primary data and introduce certain procedures for their processing to obtain reasonably accurate estimates. Broadly speaking, the procedures used by the CIS countries rely on the recommendations of the international manual on measuring nonobserved economy. However, the implementation of all the recommendations requires solutions to a number of organizational problems associated with obtaining reliable figures. The analysis of the ratio of the nonobserved economy to GDP also reveals considerable differences among the CIS countries, and it is not immediately clear whether these differences reflect the economic reality of these countries or result from problems with collecting primary data and methods of their processing.

Another common problem in the compilation of the national accounts in CIS countries is associated with the lack of harmonization of the SNA and government finance statistics (GFS), as formulated in the 2001 International Monetary Fund (IMF) manual. This lack of harmonization forces countries to use as a source of primary data the reports on execution of state budget, definitions and classifications of which differ from those in the SNA. The statistical offices also are obliged to employ some conventions and arbitrary estimates. As a result, the figures on output and final consumption expenditure by government, and hence GDP, may be distorted. The extent of this distortion may vary considerably by country.

There are also several problems with the calculation of the deflators used to obtain GDP in constant prices. The first is that the national consumer price indexes (CPIs) used for the deflation of final household consumption expenditure are inconsistent with international standards. A second problem is the lack of reliable deflators for exports and imports. A third problem is that the deflators used for the computation of nonmarket services do not take into account changes in productivity, and therefore their use produces distorted figures. A fourth

problem is the lack of reliable deflators for intermediate consumption. To some extent, this problem arises due to a lack of data on the commodity structure of intermediate consumption and the inconsistency between the commodity structure of intermediate consumption, when this data is available, and the price indices. In summary, the transition from the MPS to the SNA resulted in new statistical problems, limitations, and constraints that make it difficult to analyze economic development over time with a sufficient degree of accuracy.

II. Review of the economic development of the republics of the former USSR, 1971–1990

General trend in economic development

During the last twenty years of the USSR, the economies of its republics as a whole developed with relatively high growth rates. For example, in 1971–1990 the NMP of twelve republics (the future CIS member states) increased twofold. For individual countries, the volume indices of NMP varied from 1,7 times in Kazakhstan to 2,8 times in Belarus. During the same period, GDP in most developed European Union (EU) countries (including France, Germany, Italy, and the United Kingdom) increased by only 1,6 to 1,8 times (see Table 1). However, throughout this period, the rate of economic growth tended to fall, and this trend characterized all the Soviet republics. Thus, the annual average volume indices of NMP for the twelve republics decreased from 105,7% in 1971–1975 to 101,4% in 1986–1990. For selected republics, they varied from 4% in Kazakhstan to 8,3% in Belarus in 1971–1975, while they ranged from 1–3% in 1986–1990 in most republics. In the Caucasian republics, the volumes of NMP decreased annually on average by 1–2%. Table 1 and Charts 1 and 2 provide detailed data on the NMP volume indices.

The systematic decrease in the economic growth of the Soviet republics took place due to a number of factors, among which the deficiencies of the centrally planned system was the most crucial. At certain stages of development of the USSR, this system allowed the accumulation and allocation of the resources necessary to specific areas essential for solving important problems, in particular, industrialization in the 1930s, the organization of the wartime economy in 1941–1945, and during the postwar recovery. However, the central planning system eventually became an obstacle for further development of the economy in raising the efficient use of the available resources. Most importantly, it had limitations in managing labor and the material resources of enterprises, in providing initiatives for taking decisions on the diversification of production and the disposal of resources, and in establishing connections with other enterprises, both inside and outside the country. The closed economy also made it difficult to expand and improve the

structure of external trade. Another consequence of the closed economy was that the USSR lagged behind more economically developed countries in technology, in using innovations, and in scientific achievements in production. Excessive defense expenditure also diverted funds and resources from investment in the economy. Sharp decreases in world oil prices in the 1980s proved to be an additional negative factor in the USSR economy.

Eventually, the scale of the economy increased and its structure became more complicated, so it became more difficult to reconcile production plans with the available labor, material, and other resources. As a result, distortions appeared in the economy characterized, most of all, by deficits in a number of important products. In an attempt to overcome the deficiencies of the central planning system, a special division in the State Planning Committee compiled input–output tables for planning purposes. However, these efforts were unsuccessful in that they neither ensured the compilation of reliable input–output tables, nor overcame the deficiencies of the central planning system.

An important shortcoming in the central planning system manifested itself in the lack of an interrelationship between the flow of goods and services and the movement of financial resources and prices. Prices on many important products established centrally by the State Planning Committee did not take into account the demands of enterprises and households, or the social costs of production. As a result, the system of price formation did not stimulate normal economic processes. At the time, several leading economists understood the flaws of the price system, proposing suggestions for its reform. At the end of the 1950s and the beginning of the 1960s, an attempt of such reform was undertaken in order to reflect supply and demand and also social cost of production. It implied the introduction of some market elements in transactions between enterprises and in the system of price formation. However, conservative officials in the government and in the Communist Party opposed the reform proposals. Moreover, the reforms covered a limited number of industrial enterprises, and could not effectively influence the entire economic system.

NMP volume indices per capita (Table 2) clearly show the differences in the economic development of the republics of the former USSR. In the republics of Central Asia and Kazakhstan, population had traditionally grown rapidly; even in relatively stable periods, population growth often exceeded NMP growth (in 1976–1980 in Turkmenistan and in 1981–1985 in Kazakhstan, Tajikistan, and Turkmenistan). As a result, the ratio of the maximum and minimum volume indices of NMP per capita amounted to 2,3, while for total NMP it was 1,6. In EU countries, this difference is not typically significant.

GDP indexes per employed person in the CIS countries varied from 259% in Belarus to 98% in Turkmenistan. Within this period in most of the republics, they followed a similar trend

of a permanent decrease. The most extensive falls were in the Caucasian region, where the average annual indices went from 104–106% in 1971–1975 to 97–98% in 1986–1990. At the same time in Kyrgyzstan and Moldova, average annual indices in 1986–1990 were higher than in other periods, and the highest among the various republics in question. These different trends were due to various factors, including variation in the number of employed persons, age, and the state of fixed assets, and their effectiveness of use. In EU countries, such as France and Italy, GDP per employed person increased by 1,6–1,7 times in 1971–1990; average annual indices within this period were also relatively stable and varied from 101,4% to 103,6% (Table 3).

Production

The most significant kinds of activity in the Soviet economy were industry and agriculture, with their share of NMP in 1970 ranging from nearly four-fifths in Moldova to about two-thirds in Kazakhstan. By 1990, the share of agriculture and industry in NMP ranged from three-quarters in Kyrgyzstan and Moldova to less than two-thirds in Armenia, Kazakhstan, Russia, Tajikistan, and Turkmenistan (Table 7). Therefore, while the NMP share of these industries had decreased over 1971–1990, it was not significant, and the growth of NMP in the republics still greatly depended on the growth of industrial and agricultural production.

Industry output covered various kinds of activities, especially mining and quarrying, manufacturing, and electricity, gas and water supply. These activities were subdivided further by the adopted industrial classification into the following branches: fuel and power industry; metallurgical industry; chemical and oil processing industry; machine building and metal working; timber, woodworking, pulp and paper industry; construction materials industry; light industry; food industry; other branches.

In 1971–1990 the growth rates of industrial output across all of the republics were rather high (the annual average ranged between 104–107%) while agricultural output increased much less (101,4% annually on average across the 12 republics). As a result, the NMP growth rates for the 12 republics averaged 103,6% annually. Within the period under consideration, annual growth rates of industrial output averaged 107–110% during 1971–1975. By 1986–1990, they had fallen to 103–105% in most of the republics and just 98–101% in the Caucasian republics. For agricultural output, the periods 1976–1980 and 1981–1985 proved more favorable, with annual average growth rates of about 2%. Tables 4 and 5 provide the volume indices of industrial and agricultural output in 1971–1990.

During 1986–1990 the growth rates of NMP fell to their lowest level (an average of 101,4% across the 12 republics) because of declining industrial production and rapid declines in

“other industries”. This grouping mostly contained the item “receipts from external trade”, which represented, in fact, the output of external trade. This item received special treatment in the NMP estimates (see the footnote on p. 5): namely, it was allocated to the republics using a top-down approach after estimating the external trade output for the USSR as a whole. In 1986–1990, the output of external trade fell sharply with the fall in world oil prices.

Disposal of net material product

Data on the ratio of final consumption and capital formation indicate the disposal of NMP on the current needs of individuals and society as a whole and on investment in future economic development. In 1970 the highest share of final consumption (about three-quarters) was in Georgia, Azerbaijan, and Ukraine, while the lowest (about two-thirds) was in Kazakhstan, Armenia, and Uzbekistan. The difference between the maximum and minimum shares of final consumption (that is, 76% in Georgia and 65% in Kazakhstan) was about 11 percentage points. By 1990, the share of final consumption increased significantly in all republics. The highest share of final consumption, now more than four-fifths, was in five of the republics (Tajikistan, Ukraine, Kyrgyzstan, Georgia, and Moldova); in the remainder, it was more than 70%. The difference between the maximum and minimum shares of final consumption (that is, 85% in Tajikistan and 71% in Armenia and Kazakhstan) was 14 percentage points (Table 9).

Individual consumption

In the 1970s and 1980s, and in accordance with the program of increasing the living standard of the population, permanent growth of wages and salaries along with social benefits took place. In 1971–1988 real income of population per capita increased in Georgia by 2,3 times, in Moldova by 2 times, in Azerbaijan, Armenia, Belarus, Russia, Kazakhstan, and Kyrgyzstan by 1,9–1,8 times, in Ukraine by 1,7 times, and in Tajikistan, Turkmenistan, and Uzbekistan by 1,5–1,6 times (Table 12). Changes in the quality of nutrition, which improved significantly in all republics, evidence the effects of this income growth. In the second half of the 1980s, consumption of the most valuable food products, such as meat products, milk, dairy, and eggs, reached its maximum. However, there were sizeable differences in the level of consumption (Table 14). In 1970 the highest annual consumption of meat products per capita was in Kazakhstan, Russia, Belarus, and Ukraine (49–50 kg), of milk and dairy in Belarus (371 kg), and of eggs in Russia (182 units). In contrast, the lowest annual consumption of meat products per capita was in Azerbaijan (26 kg), and of milk and dairy, as well as eggs in Tajikistan (only 126 kg and 44 units, respectively).

By 1990, the highest annual consumption of meat products per capita was now in Belarus and Russia (75 kg), of milk and diary in Armenia (446 kg), and of eggs in Belarus (323 units). The lowest consumption of meat products was now in Tajikistan, Uzbekistan, and Azerbaijan (26–32 kg), of milk and diary in Tajikistan (161 kg) and of eggs in Turkmenistan (101 units). Importantly, the ratio of the highest and lowest level of consumption for meat products had increased from 1,9 in 1970 to 2,9 in 1990, and from 4,1 to 3,2 for eggs. On the whole, personal consumption during 1971–1990 increased in Tajikistan, Turkmenistan, and Uzbekistan by 2,6 times, in Moldova and Kyrgyzstan by 2,5–2,4 times, in Azerbaijan, Armenia, and Kazakhstan by 2,2 times, and in Russia, Belarus, Georgia, and Ukraine by 2 times (Table 11).

During the 1970s and the 1980s there was considerable effort in the development of institutions providing non-market individual services (healthcare, physical culture and sport, education, culture and art). As a result, total final consumption of population, which in addition to personal consumption included material consumption of the units providing individual non-material services, grew faster than personal consumption. In 1971–1989, it increased in Moldova, Tajikistan, Turkmenistan, and Uzbekistan by 2,6 times, in Kyrgyzstan by 2,5 times, in Armenia by 2,3 times, in Azerbaijan, Belarus, and Kazakhstan by 2,2 times, in Georgia by 2,1 times, and in Ukraine by 2 times (Table 11). However, during 1971–1990 the growth rates of real income of population per capita and personal and total final consumption of population permanently decreased. That is, they followed the same declining trend as the growth rates of NMP. For example, average annual growth rates of real income per capita for the USSR decreased from 104,4% in 1971–1975 to 102,3% in 1986–1988 (Table 12). The growth rates of personal consumption for the 12 republics also decreased from 105,4% in 1971–1975 to 102,8% in 1986–1989, while for total final consumption of population they fell from 105,6% to 103,1% (Table 11). As a result, during 1971–1990 in all republics the share of both personal and total consumption of population in total final consumption decreased at the same time as the gap between the highest and lowest shares widened.

In 1970 in most of the republics, the share of personal consumption was about 90%, with a difference between the highest share (92,2% in Belarus) and the lowest (87,1% in Russia) equal of some 5,1 percentage points. The share of total consumption of population in most of the republics was then about 98%, with the difference between the highest share (99% in Belarus) and the lowest (95,6% in Russia) equal to 3,4 percentage points (Table 10). By 1990 the share of personal consumption varied between 89,5% in Azerbaijan and 82,8% in Russia (the difference now equaled 6,7 percentage points), while the share of total final consumption of population ranged between 97,9% in Kyrgyzstan and 93,2% in Russia (the difference now equaled 4,7 percentage points) (Table 10).

Collective consumption

In 1970 expenditure on collective consumption in most of the republics equaled about 2% of final consumption, with shares ranging between 4,4% in Russia to 1% in Belarus. In 1990 the share of collective consumption increased in all republics: in Russia by up to 6,8%, in Turkmenistan, Armenia, Kazakhstan, and Georgia by 3,1–3,7%, in Azerbaijan, Belarus, Moldova, Tajikistan, Uzbekistan, and Ukraine by 2,3–2,9%. Kyrgyzstan had the lowest share (2,1%), which had remained at the 1970 level (Table 10).

Although expenditure on collective consumption represented the smallest share of final consumption, its growth rate exceeded the growth rate of the other components. In 1971–1989 collective consumption in the 12 republics increased by 3,7 times, while personal and total consumption of population increased correspondingly by just 2 and 2,1 times (Table 11). However, when analyzing the data on collective consumption expenditure, we should recall that the bigger part of collective consumption was computed for the USSR as a whole, and then distributed among the republics using a top-down approach.

Capital formation

Investment in fixed capital in 1971–1990 increased in most of the republics by 2–2,6 times: in Belarus it increased by 3 times and in Armenia by 4 times. In Armenia, the high growth rates resulted from large-scale restoration works following the catastrophic 1988 earthquake. Within this period the highest growth rates of investment in fixed capital were in 1971–1975 (average annual growth rates for the 12 republics equaled 106,9%) and in 1986–1990 (105,2%). In 1976–1985 the growth rates ranged between 103,3 and 103,5% (Table 6). However, despite the relatively high growth rates of investment in fixed capital, net fixed capital formation increased much more slowly due to growth in wear and tear. In 1971–1989 net fixed capital formation increased in the 12 republics by 1,3 times, ranging from 2 times in Uzbekistan to 0,1 in Ukraine (Table 11). The significant differences in the trend of net fixed capital formation in the republics depended on a number of factors, in particular, the age and industrial structure of the fixed assets affected the magnitude and dynamics of wear and tear. The ratio of net capital formation in total of final consumption and net capital formation in 1971–1990 decreased in all republics, while the republic-level variation increased. In 1970, it varied between 35% in Kazakhstan and 24% in Georgia (a difference of 11 percentage points). By 1990 it ranged between 29,1% in Kazakhstan and Armenia and 14,6% in Tajikistan (the difference was now up to 14,5 percentage points) (Table 9).

Concluding remarks

The data on the principal macroeconomic indicators considered above make it possible to arrive at some conclusions about the predominant trends in the social and economic development of the 12 republics of the former USSR throughout the period 1971–1990. In the 1970s, favorable development conditions existed in many of the republics because of the discovery of large subsoil assets of oil and gas, and because of high prices for oil in the world market. The flow of extra income from oil exports provided a basis for improving the living standards of the population, although the conservative and inefficient management of the economy was incapable of directing this income to restructuring the economy and renovating its technical and technological potential. However, the closed economy did not act against its dependence on the world economy. Thus, the fall of world oil prices in the 1980s stopped the flow of income from oil exports, and negatively affected the general economic situation in the USSR and led to a slowing of growth rates in all of the republics. Moreover, despite the fact that the economic development of the republics was under a common economic policy, differentiation among the republics in terms of growth rates and structural indicators had increased substantially by the end of the 1980s.

III. Review of economic development of the CIS countries, 1991–2008

Economic reforms initiated in the CIS countries at the beginning of 1990s resulted in significant changes in the organization of economic life, and resulted in the institutional and structural transformation of their economies. Several factors contributed to this transformation. These included the privatization of state property and the resulting emergence of new types of institutional units and sectors, a new role of government in the management and regulation of the economy, a new role of banks and financial institutions, new price formation mechanisms, and new methods of financing investments. They also resulted in a policy for their integration into the world economy. The liberalization of external trade was also an important feature of changes in the organization of economic life. However, there was also the disruption or at least the considerable weakening the economic ties between the former USSR republics, and this made it difficult for them to cooperate at the enterprise level. The managers of these enterprises also needed time to adapt to the new methods of running their business. All these changes had a clear negative impact on major aspects of economic and social development throughout the 1990s: indeed, their effects are still being felt today.

We can characterize the period up to the middle of the 1990s as a deep economic crisis that affected all aspects of economic life and manifested itself in sharp decreases in GDP, industrial output, and investment, galloping inflation, increasing state budget deficits, and the growth of domestic and external indebtedness. An especially considerable decrease in the rate of economic development occurred during the period from 1992 to 1994. During this period, the GDP of the CIS countries as a whole decreased by 40% compared with 1991, industrial output decreased by 50%, and investment fell by more than 70%.

For analytical purposes, it is convenient to subdivide the period from 1991 to 2008 into four subperiods: 1991–1995; 1996–2000; 2001–2005; and 2006–2008. The first sub-period from 1991 to 1995 witnessed a considerable reduction in the major macroeconomic indicators. The average annual decline in the rate of growth of GDP during this period was about 10%, but there were noticeable variations in the production decline across individual countries. The most dramatic declines were in Georgia (22%), Tajikistan (18%), Moldova (17%), Azerbaijan (16%), and Ukraine (14%). Relatively fewer declines were registered in Uzbekistan (4%), Belarus (8%), Kazakhstan (9%), and Russia (9%). Table 15 and Chart 4 illustrate the dramatic falls in the rates of economic growth in all the CIS countries.

For the CIS countries as a whole, and in individual countries, there was also a considerable decrease in the output of industry and agriculture during this period (Tables 20 and 22). The average annual decline of industrial output in the CIS countries as a whole amounted to

13%, while the average annual decline of agricultural output amounted to 8%. Deterioration in production accompanied by high rates of inflation also resulted in a sharp decrease in the standard of living. For example, during this period consumer prices increased annually in Russia by 5 times, in Armenia by 9 times, in Belarus by 9 times, and in Ukraine by 14 times (Table 33). The consumption of the main food products per capita decreased sharply across all CIS countries. For example, the consumption of meat products per capita decreased in Azerbaijan from 32 kg in 1990 to just 15 kg in 1995. The respective figures for some other CIS countries are as follows: from 44 to 25 kg in Armenia, from 75 to 58 kg in Belarus, from 75 to 55 kg in Russia, and from 68 to 39 kg in Ukraine (Table 14).

A considerable deterioration of the major sociodemographic indicators occurred during this period in practically all CIS countries. For instance, the crude rate of natural increase for the CIS countries as a whole went from 6 per 1,000 population in 1991 to -0,2 per 1,000 population in 1995. In some countries, the decrease in the rate of natural increase was particularly drastic. For example, in Russia it fell from 0,7 per 1,000 population in 1991 to -5,7 in 1995. In some CIS countries, there was also a decrease in life expectancy at birth, with especially noticeable declines in Russia, Kazakhstan, Kyrgyzstan, Moldova, and Ukraine.

During the second subperiod from 1996 to 2000, the CIS countries managed to secure modest economic growth. The annual average GDP growth rate in the CIS countries as a whole during this period was around 102%, while in some countries, such as Azerbaijan, the GDP growth rate was noticeably higher than the CIS average (Table 15). The financial crisis in Russia in 1998 suspended the stabilization of economic development during this period, and this affected some other CIS countries. Because of the financial crisis, the Russian currency devalued considerably, some commercial banks went bankrupt, and the population lost considerable savings and foreign currency deposits. However, the impact of the financial crisis on the real sector was relatively limited. Moreover, the devaluation of the Russian currency stimulated Russian exports, and this positively affected production in export-oriented industries. The rates of inflation remained rather high; however, they were considerably lower than in the previous subperiod. To sum up, by the end of the 1990s the CIS countries had managed to overcome the crisis and had begun to create the conditions for economic recovery after 2000.

The third subperiod, covering the years 2001 to 2005, was relatively successful. In all CIS countries, average annual rates of economic growth were rather high. On average for the CIS as a whole, the annual growth rate of GDP amounted to 7%, while in some countries, such as Azerbaijan, Armenia, and Kazakhstan, they were even higher, sometimes exceeding 10% (Table 15). A number of factors contributed to this growth, including favorable external conditions (relatively high prices for oil, gas, and metals stimulated exports and secured income

for state budgets), and some growth of investment (the average annual growth rate of investment in fixed capital for CIS countries amounted to 12%, whereas for the period 1996–2000 the comparable index decreased by 1,5% (Table 23)). There were also some improvements in productivity during this period.

During this time, the CIS countries managed to secure a considerable increase in the production of oil and gas (Table 21). For instance, the production of oil in Azerbaijan increased from 14 mln. tons in 2000 to 22,2 mln. tons in 2005. In Kazakhstan, the production of oil grew from 35,3 mln. tons in 2000 to 61,5 mln. tons in 2005. In Russia, oil production increased from 324 mln. tons to 470 mln. tons. Gas production also increased in a number of the CIS countries in this period, but especially in Kazakhstan where it grew by 2,2 times and in Russia (which produces about 80% of total CIS output) where it grew by 10%. Russia and Kazakhstan, as the main producers of coal in the CIS, also achieved a considerable increase in coal production during this period.

External trade grew faster than in the previous subperiod. Thus, the average annual increase in exports for the CIS as a whole amounted to 119% compared with 106% during the previous subperiod (Table 24). A substantial part of this increase was due to an increase in prices. Equally high rates of increases in imports are characteristic of this subperiod (Table 25).

Accordingly, during this subperiod the rates of economic growth in the CIS countries were considerably higher than in the majority of countries in the European Union. The table below illustrates these developments.

United Kingdom	102,4	104,5	107,2	110,9	111,9

During the subperiod from 2006 to 2008 the CIS countries managed to maintain relatively high rates of economic growth, and the annual growth of GDP during this period was somewhat higher than during the previous subperiod: now about 7,4% annually (Table 15). However, we should note that 2008 was not particularly homogeneous for the CIS in terms of economic growth. During the first nine months, practically all CIS countries had relatively high rates of growth in the major macroeconomic indicators, and some of the countries that were major exporters of oil, gas, and mineral resources earned considerable income. However, in the last quarter of 2008, the economic situation deteriorated due to the impact of the deepening global financial crisis, particularly from the decrease in external trade prices and the outflow of foreign capital. As a result, in 2008 the rates of growth of the major macroeconomic indicators in the majority of CIS countries were lower than in 2007. Thus, GDP in the CIS countries increased

by 5% in 2008 compared with 8,5% in 2007, industrial output increased by only 2% compared with 7% the previous year, and investment increased by just 10% compared with 21% in 2007. The rate of inflation was higher (17% in 2008 versus 10% in 2007). The intention was that high credit rates would cope with inflation, but at the same time enterprises had to pay considerable amounts of money for borrowing, and this did not stimulate economic growth. At the same time, it is worth noting that rates of economic growth in many developed industrial countries in 2008 were lower than in the CIS. The forecasts for 2009 are uncertain, and there is a noticeable difference in the estimates produced by the different international organizations. At present, the IMF forecast for the CIS region is a reduction in GDP of 0,4%.

The period from 1991 to 2008 as a whole

It is worth noting that the CIS possesses considerable material and labor resources. It occupies 16,4% of the world territory, on which 4,4% of the world's population resides. The CIS also possesses about 20% of the world's resources of oil, 40% of natural gas, 25% of coal, 25% of forest stocks, 11% of renewable water resources, and 13% of arable agricultural land. The CIS countries produce about 10% of the world's electrical energy. At the same time, the CIS countries produce just 4,1% of global GDP. Thus, a mere comparison of these figures shows that the CIS possesses considerable resources, but these are not efficiently in production.

When summarizing the economic development of the CIS countries during the period from 1991 to 2008, we should emphasize that an overall assessment of achievements provides a contradictory picture. On the positive side, major market mechanisms are now established and the institutional structure of the CIS economies is somewhat similar to that of the market economies. In the majority of CIS countries the corporations sector (both financial and non-financial) accounts for more than 60% of the economy, while in Russia, Azerbaijan, Belarus, and Kazakhstan its share is more than 70% (Table 28). Noticeable changes have also occurred in the industrial structure of the economies. For instance, in the majority of the CIS countries, the growth rates of services have surpassed the growth rates of goods, and the share of services in the economy has tended to increase: in 2007, it varied between 23% in Azerbaijan and more than 65% in Georgia and Moldova (table 26). However, there are noticeable differences between the countries in terms of changes in the structure of disposition of GDP (Table 29). Thus, in countries such as Azerbaijan, Belarus, Kazakhstan, and Tajikistan the share of gross capital formation in GDP increased, while in some other countries (Armenia, Moldova, Russia, Ukraine) it either did not change or decreased. Nonetheless, the CIS countries succeeded in balancing their state budgets with relatively low deficits or even surpluses (Table 35). The

majority of CIS countries also maintained their external indebtedness (as a percentage of GDP) at an acceptable level (Table 36).

There were some measures of success in the integration of the CIS countries into the world economy, including the considerable expansion of external trade, growing attraction for foreign investment, and the increase in lending and borrowing transactions with foreign countries. Thus, exports of goods by the CIS countries in 2008 increased by 665% compared with 1995. At the same time, the commodity structure of exports was changing very slowly, and exports of mineral products continued to occupy a large share of exports in 2007, especially in countries like Azerbaijan, Kazakhstan, and Russia (82%, 70%, and 65%, respectively). Conversely, the share of exports of machinery in 2007 was less than 10% for the CIS as a whole, varying between 0,5% in Tajikistan and 10% in Ukraine.

At the same time the CIS countries possess many characteristics of economies in transition. This implies that some reforms intended to transit to the market economy are not yet completed. In particular, the efficiency of the financial system in many CIS countries lags far behind developed market economies. Economic achievements during this period were also modest. In 2008, the GDP of the CIS countries as a whole grew by only 10% compared with 1990 (Table 15). In contrast, the GDP of countries in the European Union increased during the same period by more than 30%. In some CIS countries, including Georgia, Kyrgyzstan, Moldova, Ukraine, and Tajikistan, GDP in 2008 was less than in 1990. Insufficient growth of investment in fixed capital is a major factor in the relatively low rates of GDP growth. Thus, the volume index of these investments for the CIS countries as a whole in 2008 was only 83% when compared to the level in 1990 (Table 23), while GDP increased by 10%. Moldova (23%) and Russia (65%) had an especially significant decrease in investment.

It is worth noting that economic reform resulted in considerable changes in the structure of the sources of investment finance. While in countries with centrally planned economies allocations from the state budget are the major source of financing investment, they fell drastically in Ukraine, Uzbekistan, Russia, Tajikistan, Moldova, and Georgia as a result of economic reform. However, the share of foreign enterprises in financing investment tended to increase in a number of CIS countries. There are still considerable differences in the rates of economic growth among countries in the CIS. These range from 206% in Azerbaijan to 57% in Moldova (Table 15). A number of factors explain these differences. These include the availability of resources, the commencing level of economic development, and the efficiency of economic and social policy implemented by the government, different impacts of favorable external conditions and different levels of involvement in the international division of labor. The

following table provides a systematic account of the major macroeconomic indicators of the CIS countries during the period from 1991 to 2008.

	2008 to 1990 (%), constant prices				2008 to 1995 (%)		Actual individual consumption per capita (using PPPs), US dollar, 2005
	GDP	Industrial output	Agricultural output	Investment in fixed capital	Consumer price indices	Exports of goods (current prices)

CIS	110	88	90	83	1329	665	6403

¹ 2005

² 2003

As is clear from the above table, the GDP volume index of Russia and the CIS as a whole is larger than the volume index of the output of industrial and agricultural activities as well as investment (which, in fact, tended to decrease for the period from 1990 to 2008). Accordingly, GDP growth resulted from the rapid increase in services output, including trade and transportation, financial services, and general administration services.

One common problem not solved in any of the CIS countries is high rates of inflation. Though there was a slowdown in the rate of CPI increase from 1996, inflation remained unacceptably high until 2008. For example, in 2008 consumer prices in the CIS countries grew by 41% from 2005 (Table 33). Another common socioeconomic problem for all CIS countries is the growing inequalities in the distribution of income. The differences between the share of income received by the richest and poorest groups of population in the CIS countries are larger than in many developed market economies, and in some CIS countries income inequality has tended to worsen during the last several years (Table 34). For example, in Russia the ratio of the income of the richest and poorest 10 percent of the population was 13,5% in 1995 and 16,8% in

2007. While there is no statistical data available on the distribution of wealth across the population, there is reason to believe that this distribution would be even more unequal.

In practically all CIS countries the consumption per capita of food products such as meat, milk products, eggs, and sugar was considerably lower in 2007 than in 1990 (Table 14). Deterioration in demographic characteristics has also been a common feature for all CIS countries during this period. This refers to characteristics such as the crude birth rate (a reduction), the number of deaths (an increase), and the natural increase in population (a decrease). Although the rate of infant mortality has tended to decrease in practically all CIS countries, it remains at a much higher level than in any developed market economies.

Further, despite some progress in the economic development of the CIS countries, their levels of GDP per capita lag far behind the leading industrial countries. The results of a global international comparison of GDP for 2005 carried out by the World Bank (Table 18) show that GDP per capita in Russia is only 28.5% of the level in the US, and even lower for other countries in the CIS. Overall, the CIS average GDP per capita is only 22% of US GDP per capita. The share of the CIS in the world economy is only around 4%. The results of a comparison also reveal considerable differences in the level of economic development among the CIS countries. While per capita GDP in Russia is 29% higher than the CIS average, the values for the other CIS countries are considerably lower than the CIS average. For example, per capita GDP in Belarus, Kazakhstan, and Ukraine are lower than the average per capita GDP in the CIS by 7%, 5%, and 39%, respectively. The CIS countries also lag considerably behind the leading industrial countries in the standard of living. For example, per capita actual individual consumption in the CIS as a whole is only 20% of the level in the US, but again in some CIS countries it is considerably lower.
