Abstract

Arrow’s celebrated theorem of social choice shows that the aggregation of individual preferences into a social ordering cannot make the ranking of any pair of alternatives depend only on individual preferences over that pair, unless the fundamental weak Pareto and non-dictatorship principles are violated. In the standard model of division of commodities, we investigate how much information about indifference surfaces is needed to construct social ordering functions satisfying the weak Pareto principle and anonymity. We show that local information such as marginal rates of substitution or the shapes “within the Edgeworth box” is not enough, and knowledge of substantially non-local information is necessary.

Key words: social choice, preference aggregation, information, independence of irrelevant alternatives, indifference surfaces.

Journal of Economic Literature Classification Numbers: D63, D71.
1 Introduction

From Arrow’s celebrated theorem of social choice, it is well known that the aggregation of individual preferences into a social ordering cannot make the social ranking of any pair of alternatives depend only on individual preferences over that pair (this is the famous axiom of Independence of Irrelevant Alternatives). Or, more precisely, it cannot do so without trespassing basic requirements of unanimity (the Pareto principle) and anonymity (even in the very weak version of non-dictatorship). This raises the following question: What additional information about preferences would be needed in order to make aggregation of preferences possible, and compatible with the basic requirements of unanimity and anonymity?

In the last decades, the literature on social choice has explored several paths and gave interesting answers to this question. The main avenue of research has been, after Sen [18] and d’Aspremont and Gevers [7], the introduction of information about utilities, and it has been shown that the classical social welfare functions, and less classical ones, could be obtained with the Arrovian axiomatic method by letting the social preferences take account of specific kinds of utility information with interpersonal comparability.

In this paper, we focus on the introduction of additional information about preferences that is not of the utility sort. In other words, we retain a framework with purely ordinal and interpersonally non-comparable preferences. The kind of additional information that we study is about the shapes of indifference surfaces, and we ask how much one needs to know about indifference surfaces so as to be able to aggregate individual preferences while respecting the unanimity and anonymity requirements. The introduction of this additional information is formulated in terms of weakening Arrow’s axiom of independence of irrelevant alternatives.

The model adopted here is an economic model, namely, the canonical model of division of infinitely divisible commodities among a finite set of agents. We chose to study an economic model rather than the abstract model that is now commonly used in the theory of social choice\(^1\) for two reasons. First, it allows a more fine-grained analysis of information about preferences, because it makes it sensible to talk about marginal rates of substitution and other local notions about indifference surfaces. Second, in an economic

\(^1\) Recollect, however, that Arrow’s initial presentations [1, 2] dealt with this economic model of division of commodities.
model preferences are naturally restricted, and by considering a restricted domain we can hope to obtain positive results with less information than under unrestricted domain.

Our first extension of informational basis is to take account of marginal rates of substitution. It turns out that such infinitesimally local information would not be enough to escape from dictatorship, and we establish an extension of Arrow’s theorem. Then, it is natural to take account of the portions of indifference surfaces in some finitely sized neighborhoods of the allocations. Based on this additional information, we can construct a non-dictatorial aggregation rule or social ordering function, but still anonymity cannot be attained.

The second direction of extending informational basis focuses on indifference surfaces “within the Edgeworth box”. More precisely, for any two allocations, we define the smallest vector of total resources that makes both allocations feasible, and take the portion of the indifference surface through each allocation in the region below the vector. The introduction of this kind of information, however, does not help us avoid dictatorship.

The third avenue relies on some fixed monotone path from the origin in the consumption space, and focuses on the points of indifference surfaces that belong to this path. The idea of referring to such a monotone path is due to Pazner and Schmeidler [16], and may be justified if the path contains relevant benchmark bundles. Making use of this additional information, and following Pazner and Schmeidler’s [16] contribution, we can construct a Paretian and anonymous social ordering function.

Our final, the largest, extension of informational basis is to take whole indifference surfaces. Given the above result, a Paretian and anonymous social ordering function can be constructed on this informational basis.

The motivation for our research draws on many strands of recent and less recent literature. Attempts to construct social ordering functions and similar objects embodying unanimity and equity requirements were made by Suzumura [19, 20] and Tadenuma [21]. The idea that information about whole indifference surfaces is sufficient, hinted at by Pazner and Schmeidler [16] and Maniquet [14], was made more precise in Pazner [15] and was revived by Bossert, Fleurbaey and Van de gaer [4] and Fleurbaey and Maniquet [8, 9] who were able to construct nicely behaved social ordering functions on this basis. Campbell and Kelly [5] recently studied essentially the same issue in an abstract model of social choice, and showed that limited information about preferences may be enough. However, their model does not
have the rich structure of economic environments, and they focus only on non-dictatorship and do not study how much information is needed for the stronger requirement of anonymity.

The paper is organized as follows. The next section introduces the framework and the main notions. The following three sections consider the four types of extensions of the informational basis of social orderings, and present the results. Section 4 concludes. The appendix contains some proofs.

2 Basic Definitions and Arrow’s Theorem

The population is fixed. Let $N := \{1, \ldots, n\}$ be the set of agents where $2 \leq n < \infty$. There are $\ell$ goods indexed by $k = 1, \ldots, \ell$ where $2 \leq \ell < \infty$. Agent $i$’s consumption bundle is a vector $x_i := (x_{i1}, \ldots, x_{i\ell})$. An allocation is denoted $x := (x_1, \ldots, x_n)$. The set of allocations is $\mathbb{R}_+^{n\ell}$. The set of allocations such that no individual bundle $x_i$ is equal to the zero vector is denoted $X$.

A preorder is a reflexive and transitive binary relation. Agent $i$’s preferences are described by a complete preorder $R_i$ (strict preference $P_i$, indifference $I_i$) on $\mathbb{R}_+^\ell$. A profile of preferences is denoted $R := (R_1, \ldots, R_n)$. Let $\mathcal{R}$ be the set of continuous, convex, and strictly monotonic preferences over $\mathbb{R}_+^{n\ell}$.

A social ordering function (SOF) is a mapping $\bar{R}$ defined on $\mathbb{R}_+^n$, such that for all $R \in \mathbb{R}_+^n$, $\bar{R}(R)$ is a complete preorder on the set of allocations $\mathbb{R}_+^{n\ell}$. Let $\bar{P}(R)$ (resp. $\bar{I}(R)$) denote the strict preference (resp. indifference) relation associated to $\bar{R}(R)$.

Let $\pi$ be a bijection on $N$. For each $x \in \mathbb{R}_+^{n\ell}$, define $\pi(x) := (x_{\pi(1)}, \ldots, x_{\pi(n)}) \in \mathbb{R}_+^{n\ell}$, and for each $R \in \mathbb{R}_+^n$, define $\pi(R) := (R_{\pi(1)}, \ldots, R_{\pi(n)}) \in \mathbb{R}_+^n$. Let $\Pi$ be the set of all bijections on $N$. The basic requirements of unanimity and anonymity on which we focus in this paper are the following.

**Weak Pareto:** $\forall R \in \mathbb{R}_+^n, \forall x, y \in \mathbb{R}_+^{n\ell}$, if $\forall i \in N, x_i P_i y_i$, then $x \bar{P}(R)y$.

**Anonymity:** $\forall R \in \mathbb{R}_+^n, \forall x, y \in \mathbb{R}_+^{n\ell}, \forall \pi \in \Pi$:

$$x \bar{R}(R)y \Leftrightarrow \pi(x) \bar{R}(\pi(R)) \pi(y).$$

Concerning the non-dictatorship form of anonymity, we only define here what dictatorship means, for convenience. Notice that it has to do only with allocations in $X$, that is, without the zero bundle for any agent.
Dictatorial SOF: A SOF $\bar{R}$ is dictatorial if there exists $i_0 \in N$ such that:

$$\forall R \in \mathcal{R}^n, \forall x, y \in X : x_{i_0} P_{i_0} y_{i_0} \Rightarrow x \bar{P}(R)y.$$ 

The traditional, Arrovian, version of Independence of Irrelevant Alternatives is:

**Independence of Irrelevant Alternatives (IIA):**

$$\forall R, R' \in \mathcal{R}^n, \forall x, y \in \mathbb{R}^{n_f}, \text{if } \forall i \in N, R_i \text{ and } R'_i \text{ agree on } \{x_i, y_i\}, \text{ then } \bar{R}(R) \text{ and } \bar{R}(R') \text{ agree on } \{x, y\}.$$

IIA requires that the social ranking of any pair of allocations depends only on agents’ binary preferences over that pair. Hence, the informational basis of construction of social orderings is very restricted.

The version of Arrow’s theorem for the present canonical model of division of commodities is due to Bordes and Le Breton [3].

**Proposition 1** (Bordes and Le Breton [3]) *If a SOF $\bar{R}$ satisfies Weak Pareto and IIA, then it is dictatorial.*

### 3 Local Extension of Informational Basis

The IIA axiom can be weakened by strengthening the premise: that is, for any two preference profiles and any pair of allocations, only when some properties about indifference surfaces associated with the two allocations coincide in addition to pairwise preferences, it is required that the social ranking over the two allocations should agree. This amounts to allowing the SOF to make use of more information about indifference surfaces when ranking each pair of allocations.

In this paper, we consider four types of extensions of the informational basis of social orderings. First, we use information about marginal rates of substitution. Economists are used to focus on marginal rates of substitution when assessing the efficiency of an allocation, especially under convexity, since for convex preferences the marginal rates of substitution determine the half space in which the upper contour set lies. Moreover, for efficient allocations, the shadow prices enable one to compute the relative implicit income shares of different agents, thereby potentially providing a relevant measure of inequalities in the distribution of resources. Therefore, taking account
of marginal rates of substitution is a natural extension of the informational basis of social choice in economic environments.

Let \( C(x_i, R_i) \) denote the cone of price vectors that support the upper contour set for \( R_i \) at \( x_i \):

\[
C(x_i, R_i) := \{ p \in \mathbb{R}^\ell | \forall y \in \mathbb{R}^\ell_+, py = px_i \Rightarrow x_i R_i y \}.
\]

When preferences \( R_i \) are strictly monotonic, one has \( C(x_i, R_i) \subset \mathbb{R}^\ell_+ \) whenever \( x_i \gg 0 \).

**IIA except Marginal Rates of Substitution (IIA-MRS):** \( \forall R, R' \in \mathcal{R}^n, \forall x, y \in \mathbb{R}_+^n, \text{ if } \forall i \in N, R_i \text{ and } R'_i \text{ agree on } \{x_i, y_i\}, \text{ and } \)

\[
C(x_i, R_i) = C(x_i, R'_i), \\
C(y_i, R_i) = C(y_i, R'_i),
\]

then \( \bar{R}(R) \) and \( \bar{R}(R') \) agree on \( \{x, y\} \).

It is clear that IIA implies IIA-MRS. The converse does not hold as an example in Appendix A.4 shows. It turns out, unfortunately, that weakening IIA into IIA-MRS cannot alter the dictatorship conclusion of Arrow’s theorem. Introducing information about marginal rates of substitution, in addition to pairwise preferences, does not make room for satisfactory SOFs.

**Proposition 2** If a SOF \( \bar{R} \) satisfies Weak Pareto and IIA-MRS, then it is dictatorial.

The proof of Proposition 2 is long and is relegated to the appendix, but here we sketch the main line of the proof. Since IIA implies IIA-MRS, Proposition 2 is a generalization of the theorem by Bordes and Le Breton [3, Theorem 3]. An essential idea of the proofs of Arrow-like theorems in economic environments (Kalai, Muller and Satterthwaite [13], Bordes and Le Breton [3], and others) is as follows: First, we find a “free triple”, that is, three allocations for which any ranking is possible in each individual’s preferences satisfying the standard assumptions in economics. By applying Arrow’s theorem for these three allocations, it can be shown that there exists a “local dictator” for each free triple. Then, we “connect” free triples in a suitable way to show that these local dictators must be the same individual.

Turning to IIA-MRS, notice first that for each free triple, IIA-MRS works just as IIA only in the class of preference profiles for which all individuals'
marginal rates of substitution at the three allocations are the same, and satisfy certain “supporting conditions”. Invoking Arrow’s theorem, we can only show that there exists a “local dictator” for each free triple in this much restricted class of preference profiles (Lemmas 4 and 5). The difficulty in the proof of Proposition 2 lies in extending “local dictatorship” over the class of all preference profiles. This requires much work to do. See Lemmas 6 and 7 in the Appendix.

Inada [12] also considered marginal rates of substitution in an IIA-like axiom, but the difference from our work is that he looked for a local aggregator of preferences, namely a mapping defining a social marginal rate of substitution between goods and individuals, on the basis of individual marginal rates of substitution. Hence, Inada requires that, for each allocation, social preferences in an infinitely small neighborhood of the allocation should not change whenever every agent’s marginal rates of substitution at the allocation remain the same. By contrast, our IIA-MRS requires that, for each pair of allocations, social preferences over that pair should not change whenever every agent’s marginal rates of substitution at each of the two allocations remain the same. There is no logical relation between Inada’s axiom and ours.

Marginal rates of substitution give an infinitesimally local piece of information about indifference surfaces at given allocations. A natural extension of the informational basis would be to take account of the indifference surfaces in some finitely sized neighborhoods of the two allocations. Define, for any given real number $\varepsilon > 0$,

$$B_\varepsilon(x_i) := \{v \in \mathbb{R}_+^\ell | \max_{k \in \{1, \ldots, \ell\}} |x_{ik} - v_k| \leq \varepsilon\}$$

Define

$$I(x_i, R_i) := \{z \in \mathbb{R}_+^\ell | z I_i x_i\}.$$  

The set $I(x_i, R_i)$ is called the indifference surface at $x_i$ for $R_i$.

The next axiom is defined for any given $\varepsilon > 0$.

**IIA except Indifference Surfaces in $\varepsilon$-Neighborhoods (IIA-IS$\varepsilon$N):**

$\forall R, R' \in \mathcal{R}^n$, $\forall x, y \in \mathbb{R}_+^{nd}$, if $\forall i \in N$, $R_i$ and $R'_i$ agree on $\{x_i, y_i\}$, and $I(x_i, R_i) \cap B_\varepsilon(x_i) = I(x_i, R'_i) \cap B_\varepsilon(x_i)$,

$I(y_i, R_i) \cap B_\varepsilon(y_i) = I(y_i, R'_i) \cap B_\varepsilon(y_i)$,

then $\bar{R}(R)$ and $\bar{R}(R')$ agree on $\{x, y\}$.
It is clear that for any given $\varepsilon > 0$, IIA-MRS implies IIA-IS\(\varepsilon\)N. Notice also that the larger is the value of $\varepsilon$, the weaker the condition IIA-IS\(\varepsilon\)N becomes.

The next proposition shows that as soon as one switches from IIA-MRS to IIA-IS\(\varepsilon\)N, the dictatorship result is avoided even if $\varepsilon$ is arbitrarily small. However, it remains impossible to achieve Anonymity even for an arbitrarily large $\varepsilon$.

**Proposition 3** For any given $\varepsilon > 0$, there exists a SOF that satisfies Weak Pareto, IIA-IS\(\varepsilon\)N, and is not dictatorial. However, for any given $\varepsilon > 0$, there exists no SOF that satisfies Weak Pareto, IIA-IS\(\varepsilon\)N and Anonymity.

**Proof.** The proof of the impossibility part is in the appendix. Here we prove the possibility part. Define $\bar{R}$ as follows: $x \bar{R}(R) y$ if either $x_1 R_1 y_1$ and $[I(x_1, R_1) \ast B_{\varepsilon}(0) \leftrightarrow I(y_1, R_1) \ast B_{\varepsilon}(0)]$, or $x_2 R_2 y_2$ and $[I(x_1, R_1) \subseteq B_{\varepsilon}(0)$ and $I(y_1, R_1) \subseteq B_{\varepsilon}(0)]$. For brevity, let $\Gamma(v)$ denote $[I(v, R_1) \subseteq B_{\varepsilon}(0)]$. Weak Pareto and the absence of dictator are straightforwardly satisfied. IIA-IS\(\varepsilon\)N is also satisfied because when $\Gamma(x_1)$ and $\Gamma(y_1)$ hold, we have $B_{\varepsilon}(0) \subseteq B_{\varepsilon}(x_1) \cap B_{\varepsilon}(y_1)$, and therefore $\Gamma(x_1)$ and $\Gamma(y_1)$ remain true if the indifference surfaces are kept fixed on $B_{\varepsilon}(x_1)$ and $B_{\varepsilon}(y_1)$. It remains to check transitivity of $\bar{R}(R)$. First, note the following property: If $\Gamma(v)$ holds and $v R_1 v'$, then $\Gamma(v')$ also holds. Assume that there exist $x, y, z \in R^m_+$ such that $x \bar{R}(R) y \bar{R}(R) z \bar{P}(R) x$. If $\Gamma(x_1), \Gamma(y_1)$ and $\Gamma(z_1)$ all hold, this is impossible because one should have $x_2 R_2 y_2 R_2 z_2 P_2 x_2$. If only one of the three conditions $\Gamma(x_1), \Gamma(y_1), \Gamma(z_1)$ is satisfied, it is similarly impossible because one should have $x_1 R_1 y_1 R_1 z_1 P_1 x_1$. Assume $\Gamma(x_1)$ and $\Gamma(y_1)$ hold, but not $\Gamma(z_1)$. Then, $y \bar{R}(R) z \bar{P}(R) x$ requires $y_1 R_1 z_1 P_1 x_1$, which implies $\Gamma(z_1)$, a contradiction. Assume $\Gamma(x_1)$ and $\Gamma(z_1)$ hold, but not $\Gamma(y_1)$. Then, $x \bar{R}(R) y \bar{R}(R) z$ requires $x_1 R_1 y_1 R_1 z_1$, which implies $\Gamma(y_1)$, a contradiction. Assume $\Gamma(y_1)$ and $\Gamma(z_1)$ hold, but not $\Gamma(x_1)$. Then, $z \bar{P}(R) x \bar{R}(R) y$ requires $z_1 P_1 x_1 R_1 y_1$, which implies $\Gamma(x_1)$, a contradiction. 

4 Extension of Informational Basis to the “Edgeworth Box”

Our second type of extension of informational basis is to focus on the portions of indifference surfaces which lie “within the Edgeworth box”. However, when considering any pair of allocations, the two allocations may need different...
amounts of total resources to be feasible. Therefore we need to introduce the following notions. For each good \( k \in \{1, \ldots, \ell\} \), define
\[
\omega_k(x, y) := \max\{\sum_{i \in N} x_{ik}, \sum_{i \in N} y_{ik}\}.
\]

Let \( \omega(x, y) := (\omega_1(x, y), \ldots, \omega_\ell(x, y)) \). The vector \( \omega(x, y) \in \mathbb{R}_+^\ell \) represents the smallest amount of total resources that makes two allocations \( x \) and \( y \) feasible. Figure 1 illustrates the construction of \( \omega(x, y) \). Then, define
\[
\Omega(x, y) := \{z \in \mathbb{R}_+^\ell \mid z \leq \omega(x, y)\}.
\]

The set \( \Omega(x, y) \subset \mathbb{R}_+^\ell \) is the set of consumption bundles that are feasible with \( \omega(x, y) \). The following axiom captures the idea that the ranking of two allocations should depend only on the indifference surfaces over the region satisfying the feasibility constraint.

IIA except Indifference Surfaces over Feasible Allocations (IIA-ISFA): \( \forall R, R' \in \mathbb{R}^n, \forall x, y \in \mathbb{R}_+^{n\ell}, \text{ if } \forall i \in N, \)
\[
I(x_i, R_i) \cap \Omega(x, y) = I(x_i, R'_i) \cap \Omega(x, y),
I(y_i, R_i) \cap \Omega(x, y) = I(y_i, R'_i) \cap \Omega(x, y),
\]
then \( \bar{R}(\mathbb{R}) \) and \( \bar{R}(\mathbb{R}') \) agree on \( \{x, y\} \).

The left figure in Figure 1 illustrates the relevant portions of indifference surfaces under IIA-ISFA, which are indicated by thick curves, while the right figure shows the relevant parts under IIA-IS\( \varepsilon \)N. One can see that in general, there is no inclusion relation between the relevant portions of indifference surfaces under IIA-ISFA and those under IIA-IS\( \varepsilon \)N. Hence, there is no logical relation between the axioms IIA-ISFA and IIA-IS\( \varepsilon \)N, either.\(^2\)

The introduction of information about indifference surfaces “in the Edgeworth box”, however, cannot help us avoid a dictatorial SOF.

**Proposition 4** If a SOF satisfies Weak Pareto and IIA-ISFA, then it is dictatorial.

The proof relies on the following lemmas. First, we define a weak form of IIA:

**Weak Independence of Irrelevant Alternatives (WIIA):** \( \forall \mathbb{R}, \mathbb{R}' \in \mathbb{R}^n, \forall x, y \in X, \text{if} \forall i \in \mathbb{N}, R_i \text{ and } R'_i \text{ agree on } \{x_i, y_i\}, \text{and for no } i, x_i I_i y_i, \text{then } \bar{R}(\mathbb{R}) \text{ and } \bar{R}(\mathbb{R}') \text{ agree on } \{x, y\}. \)

A key lemma to prove Proposition 4 is the following:

**Lemma 1** If a SOF \( \bar{R} \) satisfies Weak Pareto and IIA-ISFA, then it satisfies WIIA.

The proof of this lemma is long and relegated in the appendix. We also define a weak form of dictatorship:

**Quasi-Dictatorial SOF:** A SOF \( \bar{R} \) is quasi-dictatorial if there exists \( i_0 \in \mathbb{N} \) such that:

\[
\forall \mathbb{R} \in \mathbb{R}^n, \forall x, y \in X : [x_{i_0} P_{i_0} y_{i_0} \text{ and } \nexists i \in \mathbb{N} \text{ with } x_i I_i y_i] \Rightarrow x \bar{P}(\mathbb{R}) y.
\]

**Lemma 2** If a SOF \( \bar{R} \) satisfies Weak Pareto and Weak IIA, then it is quasi-dictatorial.

**Proof.** Let \( \bar{R} \) be a SOF that satisfies Weak Pareto and Weak IIA. By an adaptation of a standard proof of Arrow’s theorem (for instance, Sen [18]), we can show that for every free triple \( Y \subset X \), there exists a quasi-dictator over

\(^2\)See counterexamples in Appendix A.4.
(Y, \mathcal{R}^n). Then, a direct application of Bordes and Le Breton [3] establishes quasi-dictatorship of \( \tilde{R} \). ■

It is interesting that in our economic environments, quasi-dictatorship is equivalent to dictatorship as the next lemma shows.

**Lemma 3** If a SOF \( \tilde{R} \) is quasi-dictatorial, then it is dictatorial.

**Proof.** Let \( \tilde{R} \) be a quasi-dictatorial SOF. Let \( x, y \in X \) and \( R \in \mathcal{R}^n \) be such that \( x_{i_0} P_{i_0} y_{i_0} \). By continuity and strict monotonicity of preferences, there exists \( x' \in X \) such that \( x_{i_0} P_{i_0} x'_{i_0} P_{i_0} y_{i_0} \) and for all \( i \in N \), either \( x_i P_i x'_i P_i y_i \) or \( y_i R_i x_i P_i x'_i \). Since \( \tilde{R} \) is quasi-dictatorial, it follows that \( x \tilde{P}(R) x' \) and \( x' \tilde{P}(R) y \). By transitivity, \( x \tilde{P}(R) y \). ■

Given these lemmas, the proof of Proposition 4 is straightforward.

**Proof of Proposition 4:** Let \( \tilde{R} \) be a SOF that satisfies Weak Pareto and IIA-ISFA. By Lemma 1, \( \tilde{R} \) satisfies WIIA. Then, by Lemmas 2 and 3, \( \tilde{R} \) is dictatorial. ■

One may define a weaker axiom than IIA-ISFA by considering a radial expansion of the “Edgeworth box,” namely \( \lambda \Omega(x, y) \) for a given \( \lambda \geq 1 \), where \( \lambda \) can be arbitrarily large. With this version, however, the same impossibility still holds as Proposition 4.

## 5 Extension of Informational Basis with a Monotone Path

The previous sections have shown that non-local information about indifference surfaces is needed to construct a satisfactory social ordering function. This does not mean, however, that a lot of information is needed. In this section we show that knowing one point in each indifference surface may be enough.

Our third way of extending information about indifference surfaces is to rely on a path

\[ \Lambda_{\omega_0} := \{ \lambda \omega_0 \in \mathbb{R}_{++}^\ell \mid \lambda \in \mathbb{R}_{++} \}, \]

where \( \omega_0 \in \mathbb{R}_{++}^\ell \) is fixed, and to focus on the point of each indifference surface that belongs to this path. The idea of referring to such a path is due to Pazner and Schmeidler [16], and may be justified if the path contains
relevant benchmark bundles. Although the choice of \( \omega_0 \) is not discussed here, it need not be arbitrary. For instance, one may imagine that it could reflect an appropriate equity notion, or it could be the bundle of the total available resources.

**IIA except Indifference Surfaces on Path \( \omega_0 \) (IIA-ISP\( \omega_0 \)):** \( \forall R, R' \in \mathcal{R}^n, \forall x, y \in \mathcal{R}^n_+ \), if \( \forall i \in N \),

\[
I(x_i, R_i) \cap \Lambda_{\omega_0} = I(x_i, R'_i) \cap \Lambda_{\omega_0},
\]

\[
I(y_i, R_i) \cap \Lambda_{\omega_0} = I(y_i, R'_i) \cap \Lambda_{\omega_0},
\]

then \( \bar{R}(R) \) and \( \bar{R}(R') \) agree on \( \{x, y\} \).

Following Pazner and Schmeidler’s [16] contribution, we can derive the next result, which means that not much information is needed to have an anonymous SOF if only we are prepared to accept an externally specified reference bundle.

**Proposition 5** For any given \( \omega_0 \in \mathcal{R}^n_+ \), there exists a SOF that satisfies Weak Pareto, IIA-ISP\( \omega_0 \) and Anonymity.

**Proof.** For each \( i \in N \), each \( R_i \in \mathcal{R} \) and each \( x_i \in \mathcal{R}_+^\ell \) let \( \alpha(x_i, R_i) \in \mathbb{R} \) be the scalar such that \( \alpha(x_i, R_i)\omega_0 I_i x_i \). By continuity and strict monotonicity of preferences, \( \alpha(x_i, R_i) \) always exists uniquely. Let \( \bar{R} \) be defined by:

\[
x \bar{R}(R) y \Leftrightarrow \min_{i \in N} \alpha(x_i, R_i) \geq \min_{i \in N} \alpha(y_i, R_i).
\]

This SOF clearly satisfies Weak Pareto and Anonymity. It also satisfies IIA-ISP\( \omega_0 \) because whenever \( I(x_i, R_i) \cap \Lambda_{\omega_0} = I(x_i, R'_i) \cap \Lambda_{\omega_0} \), we have \( \alpha(x_i, R_i) = \alpha(x_i, R'_i) \). \[\blacksquare\]

By relying on the lexicin criterion rather than the maximin for the SOF defined in the above proof, we could have the strong Pareto property as well: \( \forall x, y \in \mathcal{R}_+^\ell, \forall R \in \mathcal{R}^n \) if \( \forall i \in N, x_i R_i y_i \), then \( x \bar{R}(R) y \) and if, in addition, \( \exists i \in N, x_i P_i y_i \), then \( x \bar{P}(R) y \).

The final extension of informational basis that we consider is to introduce whole indifference surfaces. This condition was already introduced and studied by Hansson [11] in the abstract model of social choice, who showed that the Borda rule, which does not satisfy the Arrow IIA condition, satisfies this constrained variant thereof. Pazner [15] also proposed it, in a study of social choice in economic environments.
IIA except Whole Indifference Surfaces (IIA-WIS): \( \forall R, R' \in \mathcal{R}^n, \forall x, y \in \mathbb{R}^n_+, \) if \( \forall i \in N, \)
\[
I(x_i, R_i) = I(x_i, R'_i), \\
I(y_i, R_i) = I(y_i, R'_i),
\]
then \( \bar{R}(R) \) and \( \bar{R}(R') \) agree on \( \{x, y\} \).

Since IIA-ISP\( \omega_0 \) (as well as every other IIA type axiom introduced so far) implies IIA-WIS, we have the following corollary.

**Corollary 1** There exists a SOF that satisfies Weak Pareto, IIA-WIS and Anonymity.

There are many examples of SOFs satisfying Weak Pareto, IIA-WIS and Anonymity. Thus, in addition to these three axioms, we may add other requirements embodying various equity principles. Notice that Strong Pareto and Anonymity already entail a version of the Suppes grading principle: for all \( R \in \mathcal{R}^n, \) all \( x, y \), if there are \( i, j \) such that \( R_i = R_j, x_i P_i y_j \) and \( x_j P_i y_i \), and for all \( h \neq i, j, x_h = y_h, \) then \( x \bar{P}(R) y \). We can also construct SOFs satisfying Strong Pareto, IIA-WIS (or IIA-ISP\( \omega_0 \)), Anonymity and the following version of the Hammond equity axiom (Hammond [10]): for all \( R \in \mathcal{R}^n, \) and all \( x, y \in \mathbb{R}^n_+, \) if there are \( i, j \) such that \( R_i = R_j, y_i P_i x_i P_i x_j P_i y_j, \) and for all \( h \neq i, j, x_h = y_h, \) then \( x \bar{P}(R) y. \)

Let us summarize below the various IIA type axioms that we have introduced, and the main results in this paper. The arrows indicate logical relations between the axioms. Weaker axioms allows SOFs to depend on more information about indifference surfaces. In the appendix we show that all the implications are strict. (The converse relations do not hold.) The dotted lines in the figure indicate borderlines between possibility and impossibility, under Weak Pareto, of Non-Dictatorship and of Anonymity.

### 6 Conclusion

The construction of a non-dictatorial Arrovian social ordering function, in a framework with purely ordinal, interpersonally non-comparable preferences, requires information about the shape of indifference surfaces that goes well beyond infinitesimally local data such as marginal rates of substitution or
data “within the Edgeworth box”. On the basis of information in some finitely sized neighborhoods, one can construct a non-dictatorial social ordering function, but still cannot have an anonymous one. Only substantially non-local information about indifference surfaces enables one to construct a Paretian and anonymous social ordering function. These are the main messages of this paper, in which we proved two extensions of Arrow’s impossibility theorem, and several possibility results. We hope that our paper, more broadly, contributes to clarifying the informational foundations in the theory of social choice.

There are limits to our work which may be noticed here, and call for further research. First, we study a particular economic model, and it would be worth analyzing the same issues in other models such as the standard abstract model of social choice or other economic models, in particular models with public goods (the case of consumption externalities in our model could also be subsumed under the case of public goods). Second, the information about indifference surfaces is a complex set of object, and our analysis is far from being exhaustive on the pieces of data which can be extracted from this set. We have focussed on what seemed to us the most natural parts of indifference surfaces to which one may want to refer in social evaluation of allocations, namely, the marginal rates of substitution, the Edgeworth box (bundles which are achievable by redistributing the considered allocations), and reference rays. But there may be other ways of considering indifference
surfaces. For instance, it would be nice to have a measure of the degree to which a given piece of information is local, and the connection between this work and topological social choice (e.g. Chichilnisky [6]) might be worth exploring. Third, there may be other kinds of interesting additional information. For instance, Roberts [17] considered introducing information about utilities and about non-local preferences at the same time, and was able to characterize the Nash social welfare function on this basis. There certainly are many avenues of research along these lines. The purpose of this paper would be well-served if it could open the gate towards these enticing avenues.

Appendix

A.1 Proof of Proposition 2

The proof of Proposition 2 relies on the following lemmas.

Proof. Let \( y \) denote the restriction of \( Y \). The proof of Proposition 2 relies on the following lemmas.

A.1 Proof of Proposition 2

Appendix

Let \( Y \subset X \) be a given finite subset of \( X \). Let \( i \in N \) be given. Define \( Y_i := \{ y_i \in \mathbb{R}^\ell_+ \mid \exists y_{-i} \in \mathbb{R}_{+}^{(n-1)\ell}, (y_i, y_{-i}) \in Y \} \). Let \( Q \) denote the set of convex cones in \( \mathbb{R}_{++}^\ell \). For each \( y_i \in Y_i \), let \( Q(y_i) \in Q \) be given. We say that the set \( Y_i \) satisfies the supporting condition with respect to \( \{ Q(y_i) \mid y_i \in Y_i \} \) if for all \( y_i \in Y_i \), all \( q \in Q(y_i) \), and all \( y'_i \in Y_i \) with \( y'_i \neq y_i \), \( q \cdot y_i < q \cdot y'_i \). Define

\[
\mathcal{R}(Y_i, \{ Q(y_i) \mid y_i \in Y_i \}) := \{ R_i \in \mathcal{R} \mid \forall y_i \in Y_i, C(y_i, R_i) = Q(y_i) \}. 
\]

The set of all preorderings on \( Y_i \) is denoted by \( \mathcal{O}(Y_i) \). For all \( R_i \in \mathcal{R} \), \( R_i|_{Y_i} \) denotes the restriction of \( R_i \) on \( Y_i \). For all \( \mathcal{R}' \subset \mathcal{R} \), let \( \mathcal{R}'|_{Y_i} := \{ R_i|_{Y_i} \mid R_i \in \mathcal{R}' \} \). For all \( x_i \in X \) and all \( R_i \in \mathcal{R} \), let \( U(x_i, R_i) := \{ x'_i \in X \mid x'_i R_i x_i \} \) denote the (closed) upper contour set of \( x_i \) for \( R_i \).

Lemma 4 If a finite \( Y_i \subset \mathbb{R}^\ell_+ \) satisfies the supporting condition with respect to \( \{ Q(y_i) \mid y_i \in Y_i \} \), then \( \mathcal{R}(Y_i, \{ Q(y_i) \mid y_i \in Y_i \})|_{Y_i} = \mathcal{O}(Y_i) \).

Proof. We have only to show that \( \mathcal{O}(Y_i) \subset \mathcal{R}(Y_i, \{ Q(y_i) \mid y_i \in Y_i \})|_{Y_i} \). Let \( R' \in \mathcal{O}(Y_i) \) be any preordering on \( Y_i \). Construct a preordering \( R_i \in \mathcal{R} \) so that the upper contour set of each \( y_i \in Y_i \) is defined as follows. Let \( x_i \in Y_i \) be such that for all \( y_i \in Y_i \), \( y_i R_i x_i \). Define \( Y_i^1 := \{ y_i \in Y_i \mid y_i R_i x_i \} \). For each \( a \in \mathbb{R}_+^\ell \) and each \( q \in \mathbb{R}^\ell_{++} \), define \( H(a, q) := \{ b \in \mathbb{R}^\ell_+ \mid q \cdot b \geq q \cdot a \} \). Let

\[
U(x_i, R_i) := \bigcap_{y_i \in Y_i^1} \left[ \bigcap_{q \in Q(y_i)} H(y_i, q) \right].
\]

Let \( I(x_i, R_i) \) be the boundary of \( U(x_i, R_i) \). Clearly, for all \( y_i \in Y_i^1 \), \( C(y_i, R_i) = Q(y_i) \). We also have that for all \( y_i \in Y_i \setminus Y_i^1 \), and for all \( x'_i \in I(x_i, R_i), y_i P_i x'_i \). Given \( \delta > 0 \), let \( (1+\delta)U(x_i, R_i) := \{ x'_i \in \mathbb{R}^\ell_+ \mid \exists a_i \in U(x_i, R_i), x'_i = (1+\delta)a_i \} \), and let \( (1+\delta)I(x_i, R_i) \) be the boundary of \( (1+\delta)U(x_i, R_i) \). For sufficiently small \( \delta \), we have that for all \( y_i \in Y_i \setminus Y_i^1 \) and all \( x'_i \in (1+\delta)I(x_i, R_i), y_i P_i x'_i \).
by continuity of preferences. Let \( z_i \in Y_1 \setminus Y_i^1 \) be such that for all \( y_i \in Y_i \setminus Y_i^1 \), \( y_i R'_i z_i \). Define \( Y_i^2 := \{ y_i \in Y_i \setminus Y_i^1 \mid y_i I'_i z_i \} \). Let

\[
U(z_i, R_i) := (1 + \delta)U(x_i, R_i) \cap \left( \bigcap_{y_i \in Y_i^2} \left( \bigcap_{q \in Q(y_i)} H(y_i, q) \right) \right)
\]

Let \( I(z_i, R_i) \) be the boundary of \( U(z_i, R_i) \). By definition, for all \( y_i \in Y_i^2 \), \( C(y_i, R_i) = Q(y_i) \). We have that for all \( y_i \in Y_i \setminus (Y_i^1 \cup Y_i^2) \) and all \( x'_i \in I(z_i, R_i) \), \( y_i P_i x'_i \). Similarly we can construct the upper contour set of each \( y_i \in Y_i \setminus (Y_i^1 \cup Y_i^2) \). By its construction, \( R_i \in \mathcal{R}(Y_i, \{Q(y_i) \mid y_i \in Y_i \}) \) and \( R_i|_{Y_i} = R'_i \). Thus, \( R' \in \mathcal{R}(Y_i, \{Q(y_i) \mid y_i \in Y_i \}) \mid_{Y_i} \). \[ \square \]

Let \( \bar{R} \) be a social ordering function. Let \( Y \subseteq X \) and \( \mathcal{R}' \subseteq \mathcal{R}^n \) be given. We say that agent \( i_0 \in N \) is a local dictator for \( \bar{R} \) over \( (Y, \mathcal{R}') \) if for all \( x, y \in Y \), and all \( R \in \mathcal{R}' \), \( x_{i_0} P_{i_0} y_{i_0} \) implies \( x \bar{P}(R) y \).

**Lemma 5** Let \( \bar{R} \) be a social ordering function satisfying Weak Pareto and IIA-MRS. Let \( Y \subset X \) be a finite subset of \( X \) such that \( |Y| \geq 3 \). Suppose that for all \( i \in N, Y_i \) satisfies the supporting condition with respect to \( \{Q(y_i) \mid y_i \in Y_i \} \). Then, there exists a local dictator \( i_0 \in N \) for \( \bar{R} \) over \( (Y, \prod_{i \in N} \mathcal{R}(Y_i, \{Q(y_i) \mid y_i \in Y_i \})) \).

**Proof.** For all \( R, R' \in \prod_{i \in N} \mathcal{R}(Y_i, \{Q(y_i) \mid y_i \in Y_i \}) \), all \( y \in Y \), and all \( i \in N \), \( C(y_i, R_i) = C(y_i, R'_i) \). Since \( \bar{R} \) satisfies IIA-MRS, we have that for all \( x, y \in Y \), and all \( R, R' \in \prod_{i \in N} \mathcal{R}(Y_i, \{Q(y_i) \mid y_i \in Y_i \}) \), if for all \( i \in N, R_i \) and \( R'_i \) agree on \( \{x_i, y_i \} \), then \( \bar{R}(R) \) and \( \bar{R}(R') \) agree on \( \{x, y\} \). By Lemma 4, for all \( i \in N, \mathcal{R}(Y_i, \{Q(y_i) \mid y_i \in Y_i \}) \mid_{Y_i} = O(Y_i) \). Hence, by Arrow’s Theorem, there exists a local dictator for \( \bar{R} \) over \( (Y, \prod_{i \in N} \mathcal{R}(Y_i, \{Q(y_i) \mid y_i \in Y_i \})) \). \[ \square \]

We say that a subset \( Y \) of \( X \) is free for agent \( i \) if \( \mathcal{R}|_{Y_i} = O(Y_i) \). It is free if it is free for all \( i \in N \). If \( Y \) contains two elements, it is a free pair. If \( Y \) contains three elements, it is a free triple. Note that a set \( \{x, y\} \) is a free pair for \( i \in N \) if and only if for some \( k, k' \in \{1, \ldots, \ell\} \), \( x_{ik} > y_{ik} \) and \( y_{ik'} > x_{ik'} \). Given two consumption bundles \( x_i, y_i \in \mathbb{R}^+_{\ell} \), define \( x_i \wedge y_i \in \mathbb{R}^+ \) as \( (x_i \wedge y_i)_k = \min\{x_{ik}, y_{ik}\} \) for all \( k \in \{1, \ldots, \ell\} \).

**Lemma 6** Let \( \bar{R} \) be a social ordering function satisfying Weak Pareto and IIA-MRS. If \( \{x, y\} \subset X \) is a free pair, then there exists a local dictator for \( \bar{R} \) over \( \{x, y\}, \mathcal{R}^n \).

---

\(^4\)Given a set \( A \), \( |A| \) denotes the cardinality of \( A \).
**Proof.** Let $\bar{R}$ be a social ordering function satisfying Weak Pareto and IIA-MRS. Let $\{x, y\} \subset X$ be a free pair. Let

$$
K_1 := \{ k \in \{1, \ldots, \ell \} \mid x_{ik} > y_{ik} \}
$$

and

$$
K_2 := \{ k \in \{1, \ldots, \ell \} \mid x_{ik} < y_{ik} \}
$$

Since $\{x, y\}$ is a free pair, $K_1, K_2 \neq \emptyset$.

**Step 1:** For each $i \in N$, we define two consumption bundles $z_i, w_i \in X$ as follows:

$$
z_i := x_i \wedge y_i + \frac{1}{2} \left[ \frac{2}{3} (x_i - x_i \wedge y_i) + \frac{1}{3} (y_i - x_i \wedge y_i) \right] \tag{1}
$$

$$
w_i := x_i \wedge y_i + \frac{1}{2} \left[ \frac{1}{3} (x_i - x_i \wedge y_i) + \frac{2}{3} (y_i - x_i \wedge y_i) \right] \tag{2}
$$

Figure 2 illustrates the bundles $x_i, y_i, x_i \wedge y_i, z_i, w_i$, and also $b_i, v_i, t_i$, which

Figure 2: Proof of Lemma 6
are defined in the next step. Let $q \in \mathbb{R}^+_+$. Then, $q \cdot y_i < q \cdot w_i$ if and only if

$$2 \sum_{k \in K_2} q_k (y_{ik} - x_{ik}) < \frac{1}{6} \sum_{k \in K_1} q_k (x_{ik} - y_{ik})$$  (3)

Since $K_1 \neq \emptyset$, the right-hand-side of (3) can be arbitrarily large as $(q_k)_{k \in K_1}$ become large, $(q_k)_{k \in K_2}$ being constant. Hence, there exists a price vector $q(y_i) \in \mathbb{R}^+_+$ that satisfies inequality (3). With some calculations, it can be shown that $q(y_i) \cdot y_i < q(y_i) \cdot z_i$ and $q(y_i) \cdot y_i < q(y_i) \cdot x_i$.

Similarly, for each $a \in \{x, z, w, y\}$, we can find a price vector $q(a) \in \mathbb{R}^+_+$ such that for all $a' \in \{x, z, w, y\}$ with $a' \neq a$, $q(a) \cdot a < q(a) \cdot a'$. Hence, the set $Y^0_i = \{x, z, w, y_i\}$ satisfies the supporting condition with respect to $\{q(x_i), q(z_i), q(w_i), q(y_i)\}$.

Let $z := (z_i)_{i \in N}$ and $w := (w_i)_{i \in N}$. Let $Y^0 := \{x, z, w, y\}$. By Lemma 5, there exists a local dictator $i_0 \in N$ for $\bar{R}$ over $(Y^0, \prod_{i \in N} R(Y^0_i, \{q(x_i), q(z_i), q(w_i), q(y_i)\}))$.

**Step 2:** We will show that agent $i_0$ is a local dictator for $\bar{R}$ over $(\{x, y\}, \mathbb{R}^n)$.

Suppose, on the contrary, that there exists a preference profile $\mathbf{R}^0 \in \mathcal{R}^n$ such that (i) $x_{i_0} P_{i_0} y_{i_0}$ and $y \bar{R}(\mathbf{R}^0)x$ or (ii) $y_{i_0} P_{i_0} x_{i_0}$ and $x \bar{R}(\mathbf{R}^0)y$. Without loss of generality, suppose that (i) holds. Let $Y^1 := \{z, w, y\}$. Since agent $i_0$ is the local dictator for $\bar{R}$ over $(Y^0, \prod_{i \in N} R(Y^0_i, \{q(x_i), q(z_i), q(w_i), q(y_i)\}))$, he is also the local dictator for $\bar{R}$ over $(Y^1, \prod_{i \in N} R(Y^1_i, \{q(z_i), q(w_i), q(y_i)\}))$. (Otherwise, by Lemma 5, there exists a local dictator $j \neq i_0$ for $\bar{R}$ over $(Y^1, \prod_{i \in N} R(Y^1_i, \{q(z_i), q(w_i), q(y_i)\}))$, and we can construct a preference profile $\mathbf{R} \in \prod_{i \in N} R(Y^1_i, \{q(z_i), q(w_i), q(y_i)\}) \subset \prod_{i \in N} R(Y^0_i, \{q(x_i), q(z_i), q(w_i), q(y_i)\}))$ such that $z_{i_0} P_{i_0} y_{i_0}$ and $w_{j} P_{j} z_{j}$. Hence we must have $z P(\mathbf{R}) w$ and $w P(\mathbf{R}) z$, which is a contradiction.)

We define two allocations $v, t \in X$ in the following steps. Let $i \in N$. First, define $b_i \in \mathbb{R}^+_+$ as follows: If for all $q \in C(x_i, R^0_i)$, $q \cdot (y_i - x_i) \geq 0$, then let $b_i := y_i$. If for some $q \in C(x_i, R^0_i)$, $q \cdot (y_i - x_i) < 0$, then let $\theta > 0$ be a positive number such that for all $q \in C(x_i, R^0_i)$, $q \cdot [y_i + \theta (y_i - x_i \land y_i) - x_i] > 0$. Since $q \in \mathbb{R}^+_+$ by strict monotonicity of preferences, and $y_i - x_i \land y_i > 0$, such a number $\theta$ exists. Then, define $b_i := y_i + \theta (y_i - x_i \land y_i)$. By definition, $b_i > y_i$, and for all $q \in C(x_i, R^0_i)$, $q \cdot (b_i - x_i) > 0$. Define

$$v_i := b_i + 2(b_i - x_i \land y_i)$$

Then, $v_i > b_i > y_i$, and for all $q \in C(x_i, R^0_i)$, $q \cdot (v_i - x_i) > 0$.

---

5With a slight abuse of notation, we are writing $q(\cdot)$ for $Q(\cdot) = \{\alpha q(\cdot) \mid \alpha > 0\}$. 

22
Next, define
\[ t_i := x_i \land y_i + \frac{1}{2} \left[ \frac{2}{3} (v_i - x_i \land y_i) + \frac{1}{3} (w_i - x_i \land y_i) \right] \]
Then,
\[ t_i = b_i + \frac{1}{6} (w_i - x_i \land y_i) > b_i \]
and for all \( q \in C(x_i, R^0) \), \( q \cdot x_i < q \cdot t_i \).

As in Step 1, we can find price vectors \( q(v_i), q(t_i) \in \mathbb{R}_+^n \) such that \( q(v_i) \cdot v_i < q(t_i) \cdot a \) for all \( a \in \{ x_i, z_i, w_i, t_i \} \), and \( q(t_i) \cdot t_i < q(t_i) \cdot a \) for all \( a \in \{ x_i, z_i, w_i, v_i \} \).

On the other hand, because \( v_i > y_i \) and \( t_i > y_i \), we have that \( q(z_i) \cdot z_i < q(z_i) \cdot a \) for all \( a \in \{ t_i, v_i \} \), and \( q(w_i) \cdot w_i < q(w_i) \cdot a \) for all \( a \in \{ t_i, v_i \} \).

So far we have shown that
(i) the set \( Y^2 := \{ x_i, t_i, v_i \} \) satisfies the supporting condition with respect to \( \{ C(x_i, R^0), q(t_i), q(v_i) \} \).
(ii) the set \( Y^3 := \{ z_i, w_i, t_i, v_i \} \) satisfies the supporting condition with respect to \( \{ q(z_i), q(w_i), q(t_i), q(v_i) \} \).

Let \( v := (v_i)_{i \in N} \) and \( t := (t_i)_{i \in N} \). Let \( Y^2 := \{ x, t, v \} \) and \( Y^3 := \{ z, w, t, v \} \). By Lemma 5, there exist a local dictator \( i_1 \in N \) for \( \hat{R} \) over \( (Y^2, \prod_{i \in N} \mathcal{R}(Y^2_i), \{ C(x_i, R^0_i), q(t_i), q(v_i) \}) \), and a local dictator \( i_2 \in N \) for \( \hat{R} \) over \( (Y^3, \prod_{i \in N} \mathcal{R}(Y^3_i), \{ q(z_i), q(w_i), q(t_i), q(v_i) \}) \). Recall that agent \( i_0 \in N \) is the local dictator for \( \hat{R} \) over \( (Y^1, \prod_{i \in N} \mathcal{R}(Y^1_i), \{ q(z_i), q(w_i), q(y_i) \}) \). Let \( R^1 \in \mathcal{R}^n \) be a preference profile such that for all \( i \in N \), \( C(x_i, R^1_i) = C(x_i, R^0_i) \), and for all \( a_i \in \{ t_i, v_i, w_i, y_i, z_i \} \), \( C(a_i, R^1_i) = \{ q(a_i) \} \), and such that
\[ x_{i_0} P^1_i z_{i_0} P^1_i w_{i_0} P^1_i t_{i_0} P^1_i v_{i_0} P^1_i y_{i_0} \]
and for all \( i \in N \) with \( i \neq i_0 \),
\[ x_i P^1_i v_i P^1_i t_i P^1_i w_i P^1_i z_i P^1_i y_i \]
Since \( R^1 \in \prod_{i \in N} \mathcal{R}(Y^1_i, \{ q(z_i), q(w_i), q(y_i) \}) \), and agent \( i_0 \) is the local dictator for \( \hat{R} \) over \( (Y^1, \prod_{i \in N} \mathcal{R}(Y^1_i, \{ q(z_i), q(w_i), q(y_i) \})) \), we have \( z \hat{P}(R^1) w \). Because \( R^1 \in \prod_{i \in N} \mathcal{R}(Y^3_i, \{ q(z_i), q(w_i), q(t_i), q(v_i) \}) \), this implies that \( i_0 = i_2 \). Hence, we have \( t \hat{P}(R^1) v \). Since \( R^2 \in \prod_{i \in N} \mathcal{R}(Y^2_i, \{ C(x_i, R^0_i), q(t_i), q(v_i) \}) \), it follows that \( i_0 = i_1 \).

Let \( R^2 \in \mathcal{R}^n \) be a preference profile such that \( x_{i_0} P^2_i v_{i_0} \) and for all \( i \in N \), \( R^2_i \{ x_i, y_i \} = R^0_i \{ x_i, y_i \} \), and \( C(x_i, R^2_i) = C(x_i, R^0_i), C(t_i, R^2_i) = C(t_i, R^0_i) \), and for all \( i \neq i_0 \), \( C(a_i, R^2_i) = C(a_i, R^0_i) \).
\{q(t_i)\}, C(v_i, R_i^2) = \{q(v_i)\} and C(y_i, R_i^2) = C(y_i, R_i^0). Since agent $i_0 \in N$ is the local dictator for $\bar{R}$ over $\{(\bar{Y}^2, \prod_{i \in N} R_i^2, \{C(x_i, R_i^0), q(t_i), q(v_i)\})\}$ and $R^2 \in \prod_{i \in N} R_i^2 \{C(x_i, R_i^0), q(t_i), q(v_i)\}$, we have that $x \bar{P}(R^2)v$. Recall that for all $i \in N$, $v_i > y_i$. Hence, by strict monotonicity of preferences, $v_i P^2 y_i$ for all $i \in N$. Because the social ordering function $\bar{R}$ satisfies Weak Pareto, we have $v \bar{P}(R^2)y$. By transitivity of $\bar{R}$, $x \bar{P}(R^2)y$. However, since $\bar{R}$ satisfies IIA-MRS, and $C(x_i, R_i^2) = C(x_i, R_i^0)$, $C(y_i, R_i^2) = C(y_i, R_i^0)$, and $y \bar{R}(R^0)x$, we must have $y \bar{R}(R^2)x$. This is a contradiction. ■

**Lemma 7** Let $\bar{R}$ be a social ordering function satisfying Weak Pareto and II-MRS. If $\{x, y, z\} \subset X$ is a free triple, then there exists a local dictator for $\bar{R}$ over $\{x, y, z\}, R_n$.

**Proof.** By Lemma 6, there exist a local dictator $i_0$ over $\{x, y\}, R_n$, a local dictator $i_1$ over $\{y, z\}, R_n$, and a local dictator $i_2$ over $\{x, z\}, R_n$. Suppose that $i_0 \neq i_1$. Let $R \in R_n$ be a preference profile such that $x_{i_0} P_{i_0} y_{i_0}$, $y_{i_1} P_{i_1} z_{i_1}$, and $z_{i_2} P_{i_2} x_{i_2}$. Then, we have $x \bar{P}(R) y \bar{P}(R) z \bar{P}(R)x$, which contradicts the transitivity of $\bar{R}(R)$. Hence, we must have $i_0 = i_1$. By the same argument, we have $i_0 = i_1 = i_2$. ■

**Proof of Proposition 2:** Let $\bar{R}$ be a social ordering function satisfying Weak Pareto and II-MRS. By Lemma 6, for every free pair $\{x, y\} \subset X$, there exists a local dictator over $\{x, y\}, R_n$. By Lemma 7 and Bordes and Le Breton [3, Theorem 2], these dictators must be the same individual. Denote the individual by $i_0$. It remains to show that for any pair $\{x, y\}$ that is not free, $i_0$ is the local dictator over $\{x, y\}, R_n$. Suppose, on the contrary, that there exist $\{x, y\} \subset X$ and $R \in R_n$ such that $\{x, y\}$ is not a free pair, and $x_{i_0} P_{i_0} y_{i_0}$ but $y \bar{R}(R)x$. Define $z_{i_0} \in R_\ell$ as follows.

**Case 1:** $\{x, y\}$ is a free pair for $i_0$.
For all $\lambda \in [0, 1]$, $\{\lambda x + (1 - \lambda) y, x\}$ and $\{\lambda x + (1 - \lambda) y, y\}$ are free pairs for $i_0$. By continuity, there exists $\lambda^*$ such that $x_{i_0} P_{i_0} [\lambda^* x_{i_0} + (1 - \lambda^*) y_{i_0}] P_{i_0} y_{i_0}$. Then, let $z_{i_0} := \lambda^* x_{i_0} + (1 - \lambda^*) y_{i_0}$.

**Case 2:** $\{x, y\}$ is not a free pair for $i_0$.
Then, for all $k \in \{1, \cdots, \ell\}$, $x_{i_0 k} \geq y_{i_0 k}$ with at least one strict inequality. Note that $y \neq 0$.

**Case 2-1:** There exists $k'$ such that for all $k \in \{1, \cdots, \ell\}$ with $k \neq k'$, $x_{i_0 k} = y_{i_0 k}$ and $y_{i_0 k'} > 0$.

Then, $x_{i_0 k'} > y_{i_0 k'} > 0$. Given $\varepsilon > 0$, define $w_{i_0} \in R_\ell^\ell$ as $w_{i_0 k'} := y_{i_0 k'}$ and for all $k \neq k'$, $w_{i_0 k} := y_{i_0 k} + \varepsilon$. For sufficiently small $\varepsilon$, we have $x_{i_0} P_{i_0} w_{i_0} P_{i_0} y_{i_0}$.
by continuity and strict monotonicity of preferences. Given \( \delta > 0 \), define \( t_i \in \mathbb{R}_+^\ell \) as \( t_{ik} := w_{ik} - \delta \) and for all \( k \neq k' \), \( t_{ik} := w_{ik} \). For sufficiently small \( \delta \), we have \( x_i P_t i_0 P_{iy_0} \), again by continuity and strict monotonicity of preferences. Moreover, \( \{ t, x \} \) and \( \{ t, y \} \) are free pairs for \( i_0 \). Then, let \( z_i := t_i \).

**Case 2-2:** There exists \( k' \) such that for all \( k \in \{1, \ldots, \ell \} \) with \( k \neq k' \), \( x_{ik} = y_{ik} \) and \( y_{ik} = 0 \).

Then, for all \( k \in \{1, \ldots, \ell \} \) with \( k \neq k', x_{ik} = y_{ik} > 0 \). Let \( k'' \neq k' \). Given \( \varepsilon > 0 \), define \( w_{i0} \in \mathbb{R}_+ \) as \( w_{i0k''} := x_{i0k''} - \varepsilon \) and for all \( k \neq k'' \), \( w_{ik} := x_{ik} \).

For sufficiently small \( \varepsilon \), we have \( x_{i0} P_{i0} w_{i0} P_{i0} y_{i0} \). Given \( \delta > 0 \), define \( t_i \in \mathbb{R}_+^\ell \) as \( t_{i0k'} := w_{i0k'} + \delta \) and for all \( k \neq k' \), \( t_{ik} := w_{ik} \). For sufficiently small \( \delta \), we have \( x_{i0} P_{i0} t_{i0} P_{i0} y_{i0} \). Moreover, \( \{ t, x \} \) and \( \{ t, y \} \) are free pairs for \( i_0 \). Then, let \( z_{i0} := t_i \).

**Case 2-3:** There exist \( k', k'' \in \{1, \ldots, \ell \} \) with \( k' \neq k'' \), \( x_{i0k'} > y_{i0k'} \) and \( x_{i0k''} > y_{i0k''} \).

Let \( k^* \) be such that \( y_{i0k^*} > 0 \). Given \( \varepsilon > 0 \), define \( w_{i0} \in \mathbb{R}_+^\ell \) as \( w_{i0k^*} := y_{i0k^*} - \varepsilon \) and for all \( k \neq k^* \), \( w_{i0k} := x_{i0k} \). For sufficiently small \( \varepsilon \), we have \( x_{i0} P_{i0} w_{i0} P_{i0} y_{i0} \). Let \( k^* \neq k^* \). Given \( \delta > 0 \), define \( t_i \in \mathbb{R}_+^\ell \) as \( t_{ik^*} := w_{ik^*} + \delta \) and for all \( k \neq k^* \), \( t_{ik} := w_{ik} \). For sufficiently small \( \delta \), we have \( x_{i0} P_{i0} t_{i0} P_{i0} y_{i0} \). Moreover, \( \{ t, x \} \) and \( \{ t, y \} \) are free pairs for \( i_0 \). Then, let \( z_{i0} := t_i \).

Next, for each \( i \neq i_0 \), let \( z_i \in \mathbb{R}_+^\ell \) be such that \( \{ z, x \} \) and \( \{ z, y \} \) are free pairs for \( i \). By the same construction as above, we can find such \( z_i \in \mathbb{R}_+^\ell \) for each \( i \). Let \( z = (z_i)_{i \in \mathbb{N}} \in \mathbb{R}_+^\ell \). Since \( i_0 \) is the dictator over all free pairs, we have that \( x P(R) z \) and \( z P(R) y \). By transitivity of \( R \), we have \( x P(R) y \), which contradicts the supposition that \( y R(R) x \).

**A.2 Proof of Proposition 3**

In order to prove the impossibility part, it is convenient to consider various possible sizes of the population. Let \( \varepsilon > 0 \) be given. Suppose, to the contrary, that there exists a SOF \( R \) that satisfies Weak Pareto, IIA-IS\( \in \mathbb{N} \) and Anonymity.

**Case \( n = 2 \).** Consider the consumption bundles \( x := (10\varepsilon, \varepsilon, 0, \ldots) \), \( y := (20\varepsilon, \varepsilon, 0, \ldots) \), \( z := (\varepsilon, 20\varepsilon, 0, \ldots) \), \( w := (\varepsilon, 10\varepsilon, 0, \ldots) \). Define preference relations \( R_1 \in \mathcal{R} \) and \( R_2 \in \mathcal{R} \) as follows.
(i) On the subset

$$S_1 := \{ v \in R_+^{\ell} \mid \forall i \in \{3, \ldots, \ell\}, v_i = 0 \text{ and } v_2 \leq \min\{v_1, 2\epsilon\} \}$$

we have

$$v R_1 v' \iff v_1 + 2v_2 \geq v'_1 + 2v'_2,$$

and on the subset

$$S_2 := \{ v \in R_+^{\ell} \mid \forall i \in \{3, \ldots, \ell\}, v_i = 0 \text{ and } v_1 \leq \min\{v_2, 2\epsilon\} \},$$

we have

$$v R_1 v' \iff v_1 + v_2 \geq 2v'_1 + v'_2.$$

(ii) On $B_\epsilon(x) \cup B_\epsilon(y)$,

$$v R_1 v' \iff v_1 + 2v_2 + \sum_{k=3}^{\ell} v_k \geq v'_1 + 2v'_2 + \sum_{k=3}^{\ell} v'_k,$$

and on $B_\epsilon(z) \cup B_\epsilon(w)$,

$$v R_1 v' \iff 2v_1 + v_2 + \sum_{k=3}^{\ell} v_k \geq 2v'_1 + v'_2 + \sum_{k=3}^{\ell} v'_k.$$

(iii) Note that the projection of $B_\epsilon(x) \cup B_\epsilon(y)$ on the subspace of good 1 and good 2, namely, $[B_\epsilon(x) \cup B_\epsilon(y)] \cap \{ v \in R_+^{\ell} \mid \forall i \in \{3, \ldots, \ell\}, v_i = 0 \}$, is included in $S_1$, and the projection of $B_\epsilon(z) \cup B_\epsilon(w)$ on the subspace of good 1 and good 2 is included in $S_2$. Since

$$(w_1 + \epsilon) + 2(w_2 - 2\epsilon) > x_1 + 2x_2$$

and

$$2(y_1 - 2\epsilon) + (y_2 + \epsilon) > 2z_1 + z_2,$$

it is possible to complete the definition of $R_1$ so that $w \ P_1 x$ and $y \ P_1 z$. Then, define $R_2$ so that it coincides with $R_1$ on $S_1$, on $S_2$, and on $B_\epsilon(a)$ for all $a \in \{x, y, z, w\}$. Similarly, it is possible to complete the definition of $R_2$ so that $x \ P_2 w$ and $z \ P_2 y$. Figure 3 illustrates this construction.

If the profile of preferences is $R := (R_1, R_2)$, by Weak Pareto we have

$$(y, x) \bar{P}(R) (z, w) \text{ and } (w, z) \bar{P}(R) (x, y).$$
If the profile of preferences is $R' := (R_1, R_1)$, by Anonymity we have

$$(y, x) \bar{I}(R') (x, y) \text{ and } (w, z) \bar{I}(R') (z, w).$$

Since $R_1$ and $R_2$ coincide on $B_\varepsilon(a)$ for all $a \in \{x, y, z, w\}$, it follows from IIA-IS$_\varepsilon$N that

$$(y, x) \bar{I}(R') (x, y) \iff (y, x) \bar{I}(R) (x, y),$$

$$(w, z) \bar{I}(R') (z, w) \iff (w, z) \bar{I}(R) (z, w).$$

By transitivity, $(x, y) \bar{P}(R) (x, y)$, which is impossible.

**Case $n = 3$.** Consider the consumption bundles $x := (10\varepsilon, \frac{2\varepsilon}{3}, 0, ...)$, $y := (20\varepsilon, \frac{4\varepsilon}{3}, 0, ...)$, $t := (15\varepsilon, \frac{2\varepsilon}{3}, 0, ...)$, $z := (\frac{2\varepsilon}{3}, 20\varepsilon, 0, ...)$, $w := (\frac{2\varepsilon}{3}, 10\varepsilon, 0, ...)$, and $r := (\frac{2\varepsilon}{3}, 15\varepsilon, 0, ...)$. Define preference relations $R_1$, $R_2$, and $R_3$ as above on the subset $S_1$, on $S_2$, and on $B_\varepsilon(a)$ for all $a \in \{x, y, z, w, t, r\}$. Complete their definitions so that $y P_1 z$, $w P_1 x$, $t P_2 r$, $z P_2 y$, $x P_3 w$, and $r P_3 t$.  

27
If the profile of preferences is \( R := (R_1, R_2, R_3) \), then by Weak Pareto we have
\[
(y, t, x) \bar{P}(R) (z, r, w) \text{ and } (w, z, r) \bar{P}(R) (x, y, t).
\]
If the profile of preferences is \( R' := (R_1, R_1, R_1) \), by Anonymity we have
\[
(y, t, x) \bar{I}(R') (x, y, t) \text{ and } (w, z, r) \bar{I}(R') (z, r, w).
\]
Since \( R_1, R_2 \) and \( R_3 \) coincide on \( B \varepsilon(a) \) for all \( a \in \{x, y, t, z, w, r\} \), it follows from IIA-IS\( \varepsilon \mathbb{N} \) that
\[
(y, t, x) \bar{I}(R') (x, y, t) \iff (y, t, x) \bar{I}(R) (x, y, t),
\]
\[
(w, z, r) \bar{I}(R') (z, r, w) \iff (w, z, r) \bar{I}(R) (z, r, w).
\]
By transitivity, \( (y, t, x) \bar{P}(R) (x, y, t) \), which is impossible.

**Case \( n = 2k \).** Partition the population into \( k \) pairs, and construct an argument similar to the case \( n = 2 \), with the consumption bundles \( x = (10 \varepsilon, \frac{2n}{n}, 0, \ldots) \), \( y = (20 \varepsilon, \frac{n}{n}, 0, \ldots) \), \( z = (\frac{2n}{n}, 20 \varepsilon, 0, \ldots) \), \( w = (\frac{2n}{n}, 10 \varepsilon, 0, \ldots) \), and the allocations \( (y, x, y, x, \ldots) \), \( (x, y, y, x, \ldots) \), \( (z, w, z, w, \ldots) \) and \( (w, z, w, z, \ldots) \).

**Case \( n = 2k+1 \).** Partition the population into \( k-1 \) pairs and one triple, and construct an argument combining the cases \( n = 2 \) and \( n = 3 \), with the consumption bundles \( x = (10 \varepsilon, \frac{2n}{n}, 0, \ldots) \), \( y = (20 \varepsilon, \frac{2n}{n}, 0, \ldots) \), \( t = (15 \varepsilon, \frac{n}{n}, 0, \ldots) \), \( z = (\frac{2n}{n}, 20 \varepsilon, 0, \ldots) \), \( w = (\frac{2n}{n}, 10 \varepsilon, 0, \ldots) \), \( r = (\frac{2n}{n}, 15 \varepsilon, 0, \ldots) \), and the allocations \( (y, x, y, x, \ldots, y, t, x) \), \( (x, y, x, y, \ldots, x, y, t) \), \( (z, w, z, w, \ldots) \), \( r, w \) and \( (w, z, w, z, z, r, w) \).

### A.3 Proof of Lemma 1

To prove Lemma 1, we need an auxiliary lemma. Define
\[
X_1 := \{ x_i \in R_i^* \setminus \{0\} \mid \forall k \geq 2, x_{ik} = 0 \}
\]
\[
X_2 := \{ x_i \in R_i^* \setminus \{0\} \mid \forall k \neq 2, x_{ik} = 0 \}.
\]

**Lemma 8** For all \( R_i \in \mathcal{R} \), and all \( x, y \in X \), there exists \( R_i^* \in \mathcal{R} \) such that
\[
I(x_i, R_i) \cap \Omega(x, y) = I(x_i, R_i^*) \cap \Omega(x, y)
\]
\[
I(y_i, R_i) \cap \Omega(x, y) = I(y_i, R_i^*) \cap \Omega(x, y)
\]
\[
I(x_i, R_i^*) \cap X_1 \neq \emptyset
\]
\[
I(y_i, R_i^*) \cap X_1 \neq \emptyset
\]
Proof. Let \( R_i \in \mathcal{R} \) and \( x, y \in X \) be given. Without loss of generality, assume that \( y_i, R_i, x_i \). Define \( A := I(x_i, R_i) \cap \Omega(x, y) \) and

\[
U(x_i, R^*_i) := \bigcap_{a \in A} \left[ \bigcap_{q \in C(a, R_i)} H(a, q) \right]
\]

where we recall that \( H(a, q) = \{ b \in \mathbb{R}^+_+ \mid q \cdot b \geq q \cdot a \} \). Let \( I(x_i, R^*_i) \) be the boundary of \( U(x_i, R^*_i) \).

Define a function \( g : A \rightarrow \mathbb{R}_+ \) as follows: For every \( a \in A \), if \( (a_1 + 1, 0, \ldots, 0) P_i a \), then let \( g(a) = 0 \), and otherwise, let \( g(a) \in \mathbb{R} \) be such that \( (a_1 + 1, g(a)a_2, \ldots, g(a)a_i) I_i a \). By continuity and strict monotonicity of \( R_i \), \( g(a) \) exists uniquely and \( 0 \leq g(a) < 1 \). By continuity of \( R_i \), \( g \) is continuous. For every \( a \in A \), let \( b(a) := (a_1 + 1, g(a)a_2, \ldots, g(a)a_i) \). Define \( f : A \rightarrow \mathbb{R}_+ \) by

\[
f(a) := a + \frac{1}{1 - g(a)} [b(a) - a]
= \left( a_1 + \frac{1}{1 - g(a)}, 0, \ldots, 0 \right).
\]

Since \( b(a) \) \( R_i a \), it follows that for every \( q \in C(a, R_i) \), \( q \cdot b(a) \geq q \cdot a \), and so \( q \cdot f(a) \geq q \cdot a \). Hence, \( f(a) \in H(a, q) \).

The function \( f \) is continuous, and the set \( A \) is compact and nonempty. Hence, the set \( f(A) \) is compact and nonempty. Therefore, there exists \( a^* \in A \) such that \( ||f(a^*)|| = \max_{a \in A} ||f(a)|| = \max_{a \in A} \left[ a_1 + \frac{1}{1 - g(a)} \right] \). Then, for all \( a \in A \), and all \( q \in C(a, R_i) \), since \( f(a) \in H(a, q) \) and \( f(a^*) \geq f(a) \), we have \( f(a^*) \in H(a, q) \). Thus, \( f(a^*) \in U(x_i, R^*_i) \), which proves that \( U(x_i, R^*_i) \cap X_1 \neq \emptyset \). By continuity and strict monotonicity of preferences, \( I(x_i, R^*_i) \cap X_1 \neq \emptyset \).

If \( y_i I_i x_i \), then we are done. Assume that \( y_i P_i x_i \). Define

\[
U(y_i, R^*_i) := \bigcap_{a \in I(y_i, R_i) \cap \Omega(x, y)} \left[ \bigcap_{q \in C(a, R_i)} H(a, q) \right].
\]

By continuity of preferences, there exists \( \delta > 0 \) such that for all \( z_i \in [(1 + \delta)I_i(x_i, R_i)] \cap \Omega(x, y) \), \( y_i P_i z_i \). Define

\[
\bar{U}(y_i, R^*_i) := U(y_i, R^*_i) \cap (1 + \delta)U(x_i, R^*_i)
\]
Then, let $I(y_i, R^*_i)$ be the boundary of $\bar{U}(y_i, R^*_i)$. Note that $I(x_i, R^*_i) \cap I(y_i, R^*_i) = \emptyset$. A similar argument as above shows that $U(y_i, R^*_i) \cap X_1 \neq \emptyset$. Since $U(x_i, R^*_i) \cap X_1 \neq \emptyset$, we have $[(1 + \delta)U(x_i, R^*_i)] \cap X_1 \neq \emptyset$. Thus, $\bar{U}(y_i, R^*_i) \cap X_1 \neq \emptyset$. By continuity and strict monotonicity of preferences, $I(y_i, R^*_i) \cap X_1 \neq \emptyset$. ■

**Proof of Lemma 1.**

Let $R, R' \in \mathcal{R}^n$, $x, y \in X$ be such that for all $i \in N$, $R_i$ and $R'_i$ agree on $\{x_i, y_i\}$, and for no $i \in N$, $x_i \neq y_i$. Assume that $x \bar{P}(R)y$.

By Lemma 8, there exists $R^* \in \mathcal{R}^n$ such that for all $i \in N$,

$$I(x_i, R_i) \cap \Omega(x, y) = I(x_i, R^*_i) \cap \Omega(x, y)$$

$$I(y_i, R_i) \cap \Omega(x, y) = I(y_i, R^*_i) \cap \Omega(x, y)$$

$$I(x_i, R^*_i) \cap X_1 \neq \emptyset$$

$$I(y_i, R^*_i) \cap X_1 \neq \emptyset,$$

and similarly there exists $R'^* \in \mathcal{R}^n$ such that for all $i \in N$,,

$$I(x_i, R'_i) \cap \Omega(x, y) = I(x_i, R'^*_i) \cap \Omega(x, y)$$

$$I(y_i, R'_i) \cap \Omega(x, y) = I(y_i, R'^*_i) \cap \Omega(x, y)$$

$$I(x_i, R'^*_i) \cap X_2 \neq \emptyset$$

$$I(y_i, R'^*_i) \cap X_2 \neq \emptyset.$$

By strict monotonicity of preferences, each of $I(x_i, R^*_i) \cap X_1$, $I(y_i, R^*_i) \cap X_1$, $I(x_i, R'^*_i) \cap X_2$, and $I(y_i, R'^*_i) \cap X_2$ is a singleton. Define $x^1, y^1 \in X^1_n$ by $\{x^1_i\} := I(x_i, R^*_i) \cap X_1$ and $\{y^1_i\} := I(y_i, R^*_i) \cap X_1$ for all $i \in N$. Notice that for all $i \in N$, $x^1_i > 0$, $y^1_i > 0$ because $x, y \in X$ and preferences are strictly monotonic. Construct $x^{1*}, y^{1*} \in X^1_n$ as follows: for all $i \in N$,

$$x^{1*}_{1i} := x^1_{1i} + \frac{1}{3}|x^1_{1i} - y^1_{1i}|$$

$$y^{1*}_{1i} := \max \left\{ \frac{1}{2}y^1_{1i}, y^1_{1i} - \frac{1}{3}|x^1_{1i} - y^1_{1i}| \right\}.$$

Notice that for all $i \in N$,

$$x^{1*}_{1i} \geq y^{1*}_{1i} \iff x_i \bar{P} y_i$$

$$y^{1*}_{1i} \geq x^{1*}_{1i} \iff y_i \bar{P} x_i.$$
By Weak Pareto, \( x^{1*} \bar{P}(R^*)x \) and \( y^{1*} \bar{P}(R^*)y \). By IIA-ISFA, \( x \bar{P}(R^*)y \). Therefore, by transitivity, 
\[
x^{1*} \bar{P}(R^*)y^{1*}.
\]

Now, define \( x^2, y^2 \in X^*_n \) by \( \{x^2_i\} := I(x_i, R^*_i) \cap X_2 \) and \( \{y^2_i\} := I(y_i, R^*_i) \cap X_2 \) for all \( i \in N \). Again, \( x^2_i > 0, y^2_i > 0 \) for all \( i \in N \). Construct \( x^{2*}, y^{2*} \in X^*_n \) as follows: for all \( i \in N \),
\[
x^{2*}_i := \max \left\{ \frac{1}{2} x^2_i, x^2_i, \frac{1}{3} |x^2_i - y^2_i| \right\}
\]
\[
y^{2*}_i := y^2_i + \frac{1}{3} |x^2_i - y^2_i|.
\]

Notice that for all \( i \in N \),
\[
x^{2*}_i > y^{2*}_i \iff x_i \bar{P}_i y_i \iff x^{1*}_i > y^{1*}_i
\]
\[
y^{2*}_i > x^{2*}_i \iff y_i \bar{P}_i x_i \iff y^{1*}_i > x^{1*}_i.
\]

By Weak Pareto, \( x \bar{P}(R^*)x^{2*} \) and \( y^{2*} \bar{P}(R^*)y \).
Let \( R^{**} \in R^n \) be such that for all \( i \in N \),
\[
x^{2*}_i P^{**}_i x^{1*}_i \text{ and } y^{1*}_i P^{**}_i y^{2*}_i.
\]

Notice that for all \( i \in N \),
\[
I(x^{1*}_i, R^{**}_i) \cap \Omega(x^{1*}, y^{1*}) = I(x^{1*}_i, R^*_i) \cap \Omega(x^{1*}, y^{1*}) = \{x^{1*}_i\},
\]
\[
I(y^{1*}_i, R^{**}_i) \cap \Omega(x^{1*}, y^{1*}) = I(y^{1*}_i, R^*_i) \cap \Omega(x^{1*}, y^{1*}) = \{y^{1*}_i\}.
\]

Therefore, by IIA-ISFA, \( x^{1*} \bar{P}(R^{**})y^{1*} \). By Weak Pareto, \( x^{2*} \bar{P}(R^{**})x^{1*} \) and \( y^{1*} \bar{P}(R^{**})y^{2*} \), so that by transitivity, \( x^{2*} \bar{P}(R^{**})y^{2*} \).

Now, we also have that for all \( i \in N \),
\[
I(x^{2*}_i, R^{**}_i) \cap \Omega(x^{2*}, y^{2*}) = I(x^{2*}_i, R^*_i) \cap \Omega(x^{2*}, y^{2*}) = \{x^{2*}_i\},
\]
\[
I(y^{2*}_i, R^{**}_i) \cap \Omega(x^{2*}, y^{2*}) = I(y^{2*}_i, R^*_i) \cap \Omega(x^{2*}, y^{2*}) = \{y^{2*}_i\}.
\]

By IIA-ISFA again, \( x^{2*} \bar{P}(R^*)y^{2*} \). By transitivity, we deduce \( x \bar{P}(R^*)y \). Finally, by IIA-ISFA,
\[
x \bar{P}(R')y.
\]

We have proved that \( x \bar{P}(R) \) implies \( x \bar{P}(R')y \). It follows from symmetry of the argument that \( y \bar{P}(R)x \) implies \( y \bar{P}(R')x \), and that \( x \bar{I}(R)y \) implies \( x \bar{I}(R')y \). \( \blacksquare \)
A.4 Logical Relations between the IIA Axioms

1. IIA-MRS implies neither IIA-ISFA nor IIA.
   Consider the following SOF: \( \forall R \in \mathcal{R}^n, x, y \in \mathbb{R}^n_+^\ast, x \bar{R}(R) y \) if and only if (i) \( \exists p \in \mathbb{R}^n_+ \) such that \( \forall i \in N, p \in C(x_i, R_i) \), and \( \forall i, j \in N, p \cdot x_i = p \cdot x_j \), or (ii) \( \not\exists p \in \mathbb{R}^n_+ \) such that \( \forall i \in N, p \in C(y_i, R_i) \), and \( \forall i, j \in N, p \cdot y_i = p \cdot y_j \).

   This SOF satisfies IIA-MRS but violates IIA-ISFA and hence IIA.

2. IIA-IS\(\varepsilon\)N implies neither IIA-ISFA nor IIA.
   This is derived from fact 1 above and the fact that IIA-MRS implies IIA-IS\(\varepsilon\)N.

3. IIA-IS\(\varepsilon\)N does not imply IIA-MRS.
   This is derived from Propositions 2 and 3.

4. IIA-WIS implies neither IIA-IS\(\varepsilon\)N nor IIA-ISFA.
   This is derived from Propositions 3, 4 and Corollary 1.

5. IIA-ISFA implies none of IIA-IS\(\varepsilon\)N, IIA-MRS and IIA.
   Fix \( \omega_0 := (1, \ldots, 1) \in \mathbb{R}^n_+ \). For each \( i \in N \), each \( R_i \in \mathcal{R} \) and each \( x_i \in \mathbb{R}^n_+ \), let \( \alpha(x_i, R_i) \in \mathbb{R}^n_+ \) be defined as in the proof of Proposition 5. Consider the following SOF: \( \forall R \in \mathcal{R}^n, x, y \in \mathbb{R}^n_+^\ast, x \bar{R}(R) y \) if and only if (i) \( \exists \lambda \in \mathbb{R}^n_+ \) such that \( \sum_{i \in N} y_i = \lambda \omega_0 \), or (ii) \( \exists \lambda, \lambda' \in \mathbb{R}^n_+ \) such that \( \sum_{i \in N} x_i = \lambda \omega_0 \) and \( \sum_{i \in N} y_i = \lambda' \omega_0 \), and \( \min_{i \in N} \alpha(x_i, R_i) \geq \min_{i \in N} \alpha(y_i, R_i) \). This SOF satisfies IIA-ISFA, but it violates IIA-IS\(\varepsilon\)N and hence IIA-MRS and IIA.

6. IIA-IS\(\varepsilon\)\(\omega_0\) implies none of IIA-IS\(\varepsilon\)N, IIA-MRS, IIA-ISFA and IIA.
   This is derived from Propositions 3, 4 and 5.

7. IIA-WIS does not imply IIA-IS\(\varepsilon\)\(\omega_0\).
   Fix \( p := (1, \ldots, 1) \in \mathbb{R}^n_+ \). For each \( i \in N \), each \( R_i \in \mathcal{R} \) and each \( x_i \in \mathbb{R}^n_+ \), define \( e(x_i, R_i) := \min\{p \cdot y_i \mid y_i \in I(x_i, R_i)\} \). (That is, \( e(x_i, R_i) \) is the minimum expenditure to attain \( I(x_i, R_i) \) at \( p \).) Consider the following SOF: \( \forall R \in \mathcal{R}^n, x, y \in \mathbb{R}^n_+^\ast, x \bar{R}(R) y \) if and only if \( \min_{i \in N} e(x_i, R_i) \geq \min_{i \in N} e(y_i, R_i) \). This SOF satisfies IIA-WIS but violates IIA-IS\(\varepsilon\)\(\omega_0\).
