OPTIMAL GROWTH UNDER UNCERTAINTY:  
A COMPLETE CHARACTERIZATION OF WEAKLY  
MAXIMAL PROGRAMS*  

SHIN-ICHI TAKEKUMA  

Abstract  

In this paper a general reduced model of capital accumulation under uncertainty is  
presented, and the existence of a price system supporting the weakly maximal program of  
capital accumulation is proved. Also, the conditions under which such a price system is a  
sequence of integrable functions are shown. In addition, the weakly maximal program is  
characterized by using a price system.  

I. Introduction  

The purpose of this paper is to prove the existence of price systems for weakly maximal  
programs of capital accumulation under uncertainty and to characterize the weak maxi-  
mality of programs. The result established in this paper is a generalization of those of  
Radner (1973) and Zilcha (1976). Also it includes the results in deterministic cases by  
McKenzie (1986).  

In the economy considered in this paper, there is uncertainty in production technologies  
and utility functions. In each period in time, the current production technology and utility  
function are certain, but future technologies and utilities thereafter are uncertain. The  
economic model presented in this paper is a general reduced form which includes many  
cases of economic application.  

In proving the existence of price systems supporting weakly maximal programs, there  
are two key arguments. One is an induction argument for the proof of existence of prices,  
which has been developed by McKenzie (1986) in deterministic models and first applied  
by Zilcha (1976) to models with uncertainty. The other is a decomposition theorem on  
finitely additive measures by Yosida & Hewitt (1952), which has been used in proving  
the integrability of prices, first by Bewley (1972) in general equilibrium models, and also  
by Radner (1973) and Zilcha (1976) in growth models with uncertainty. In their growth  
models, uncertainty exists only in production technologies and is assumed to be stationary.

* This paper was presented at the meeting on nonlinear analysis and mathematical economics at Research Institute for Mathematical Sciences, Kyoto University, Kyoto, in November, 1991.
In this paper we shall consider a general non-stationary model with uncertainty in both production technology and utility, and prove a general support price theorem for weakly maximal programs of capital accumulation.

This paper is formulated in the following fashion. In section 2 we shall construct a general reduced model of capital accumulation under uncertainty. In section 3 an existence theorem of a price system for the weakly maximal program will be proved. In section 4 the conditions under which price systems are integrable functions will be shown. In section 5 the weakly maximal program will be characterized by a price system.

II. A General Reduced Model

First we shall present a general reduced model of capital accumulation in which future utilities and production technologies are uncertain.

Let $(\Omega, \mathcal{F}, P)$ be a probability space. Each element in $\Omega$ denotes a possible state of nature, which may be interpreted as a stream of environments in all past, present, and future periods. Family $\mathcal{F}$ is the set of all possible events and $P$ denotes the probability distribution of states.

Let $T=\{0, 1, 2, \ldots\}$ be the space of time. The uncertainty of states is described by a filtration $\{\mathcal{F}_t | t \in T\}$, i.e., $\mathcal{F}_t$ is a $\sigma$-sub-algebra of $\mathcal{F}$ such that $\mathcal{F}_t \subseteq \mathcal{F}_{t+1}$ for all $t \in T$. Each family $\mathcal{F}_t$ is interpreted as the information about states that will become known up to period $t$.

The production technology available at each period $t>0$ is described by a relation $D_t: \Omega \rightarrow \mathbb{R}^m \times \mathbb{R}^m$, that is,

$$\omega \in \Omega \mapsto D_t(\omega) \subseteq \mathbb{R}^m \times \mathbb{R}^m,$$

where $\mathbb{R}^m$ denotes an $m$-dimensional Euclidean space. We assume that the graph of $D_t$ defined by

$$G(D_t) = \{(x, y, \omega) | (x, y) \in D_t(\omega)\},$$

is $\mathcal{B}(\mathbb{R}^m) \times \mathcal{B}(\mathbb{R}^m) \times \mathcal{F}_t$-measurable, where $\mathcal{B}(\mathbb{R}^m)$ is the family of all Borel subsets of $\mathbb{R}^m$. By $D_t(\omega)$ we represent the possibility of transformation of capital stocks. That is, $(x, y) \in D_t(\omega)$ means that under state $\omega$ it is possible to transform capital stock $x$ at time $t-1$ into capital stock $y$ at time $t$.

The satisfaction in the economy at each period $t>0$ is described by a utility function $u_t: G(D_t) \rightarrow \mathbb{R} \cup \{-\infty\}$, that is,

$$(x, y, \omega) \in G(D_t) \mapsto u_t(x, y, \omega) \in \mathbb{R} \cup \{-\infty\},$$

where $\mathbb{R}$ denotes the real line. We assume that $u_t$ is a $\mathcal{B}(\mathbb{R}^m) \times \mathcal{B}(\mathbb{R}^m) \times \mathcal{F}_t$-measurable function, which may take value $-\infty$. Value $u_t(x, y, \omega)$ is interpreted as the maximum level of social welfare under state $\omega$ attained in period between time $t-1$ to time $t$ if capital stocks at time $t-1$ and time $t$ are $x$ and $y$ respectively.

In order to show a program of capital accumulation, we will use a stochastic process,
i.e., a function $K: T \times \Omega \rightarrow \mathbb{R}^m$ such that $K(t, \cdot)$ is $\mathcal{F}_t$-measurable for each $t \in T$. To denote a stochastic process $K: T \times \Omega \rightarrow \mathbb{R}^m$, we also write as $K=\{k_t|t \in T\}$, where $k_t$ is a function defined by $k_t(\omega)=K(t, \omega)$. In addition, we shall restrict ourselves only to essentially bounded processes, and namely assume that $k_t \in L_\infty(\mathcal{F}_t)$ for all $t \in T$, where $L_\infty(\mathcal{F}_t)$ is the set of all essentially bounded $\mathcal{F}_t$-measurable functions on $\Omega$ to $\mathbb{R}^m$ with respect to $P$.

The set of all possible ways to transform capital stocks from time $t-1$ to time $t$ is defined by

$$\mathcal{D}_t = \{(f, g) \in L_\infty(\mathcal{F}_{t-1}) \times L_\infty(\mathcal{F}_t) | (f(\omega), g(\omega)) \in D_t(\omega) \text{ a.s.}\}.$$ 

Definition 2.1: A stochastic process $K=\{k_t|t \in T\}$ is called a program if $k_t \in L_\infty(\mathcal{F}_t)$ and $(k_{t-1}(\omega), k_t(\omega)) \in D_t(\omega)$ a.s. for each $t > 0$, i.e., $(k_{t-1}, k_t) \in \mathcal{D}_t$ for all $t > 0$.

In a program $K=\{k_t|t \in T\}$, for each $t \in T$, $k_t$ is a random variable and $k_t(\omega)$ denotes quantities of capital stock planned to accumulate at time $t$ in state $\omega$. Since $D_t$ is $\mathcal{B}(\mathbb{R}^m) \times \mathcal{B}(\mathbb{R}^m) \times \mathcal{F}_t$-measurable, production technology $D_t$ is perfectly known in determining capital stock $k_t$ at time $t$. However, in determining $k_{t-1}$ at time $t-1$, production technology $D_t$ is unknown. In this sense, uncertainty exists in production technologies. Similarly, utility function $u_t$ is perfectly known in determining capital stock $k_t$ at time $t$, but unknown in determining $k_{t-1}$ at time $t-1$. Thus, uncertainty also exists in utility functions.

For a program $K=\{k_t|t \in T\}$, we denote, by $U_t(K)$, the sum of expected utilities that will be obtained up to time $t$ by program $K$. Namely, under some appropriate conditions which will be shown later, we can define

$$U_t(K) = \sum_{s=1}^{t} \int u_t(k_{s-1}(\omega), k_s(\omega), \omega) dP(\omega).$$

Since value $U_t(K)$ may become infinity as $t$ goes to $+\infty$, the so-called overtaking criterion should be used to evaluate programs.

Definition 2.2: A program $K=\{k_t|t \in T\}$ is said to be weakly maximal if any other program starting from the same initial condition can not overtake program $K$, i.e., there is no other program $K'=\{k'_t|t \in T\}$ with $k_0=k'_0$ such that

$$\lim_{t \to +\infty} \inf [U_t(K') - U_t(K)] > 0.$$ 

The above definition is a generalization of maximization in usual problems where utility sums are bounded.

### III. Price Systems Supporting Weakly Maximal Programs

In this section we shall establish a general version of the support price theorem. The following are basic assumptions for the model.
(A.1) (convexity) For each \( t \) and \( \omega \), \( D_t(\omega) \) is convex and \( u_t(x, y, \omega) \) is concave in \( (x, y) \).

(A.2) (boundedness) For each \( t \), for any \( \alpha > 0 \) there exists a number \( \beta \) such that \( (x, y) \in D_t(\omega) \) and \( ||x|| \leq \alpha \) imply \( ||y|| \leq \beta \) and \( u_t(x, y, \omega) \leq \beta \).

Assumption (A.1) is the convexity of the model, and means that production sets are convex and utility functions are concave. Assumption (A.2) is the boundedness of the model in each period, and means that, if capital stock at time \( t-1 \) is bounded, then capital stock and utility at time \( t \) are also bounded.

Remark 3.1: Assumption (A.2) implies that given \( f \in L_2(\mathcal{F}_{t-1}) \), there exists a number \( b_0 \) such that \( ||g||_\infty \leq b_0 \) and \( \int u_t(f, g, \cdot) dP \leq b_0 \) for all \( g \) with \( (f, g) \in \mathcal{D}_t \).

We do not have to take into consideration programs which are obviously bad. Let us consider a program \( K^* = \{ k^*_t | t \in T \} \) satisfying the following condition.

(C.1) \( \int u_t(k^*_{t-1}, k^*_t, \cdot) dP > -\infty \) for each \( t > 0 \).

Remark 3.2: Under assumption (A.2), condition (C.1) implies that in program \( K^* \), \( \int u_t(k^*_{t-1}, k^*_t, \cdot) dP \) is finite for each \( t > 0 \). Thus, value \( U_t(K^*) \) is well-defined, and the definition of weak maximality can be applied to program \( K^* \).

Given program \( K^* \), for each \( t \in T \) let us define a normalized utility function, \( v_t : G(D_t) \to R \cup \{-\infty\} \), by

\[ v_t(x, y, \omega) = u_t(x, y, \omega) - u_t(k^*_{t-1}(\omega), k^*_t(\omega), \omega). \]

For each \( t \in T \) and \( f \in L_2(\mathcal{F}_t) \), we denote by \( \mathcal{H}_t(f) \) the set of all feasible programs beginning with capital stock \( f \) at time \( t \), i.e.,

\[ \mathcal{H}_t(f) = \{ K = \{ k_t | t \in T \} | K \text{ is a stochastic process such that } k_t = f \text{ and } (k_s, k_{s+1}) \in \mathcal{D}_{s+1} \text{ for each } s \geq t \}. \]

Now, by virtue of Remark 3.2, we can define a normalized value function. For each \( t \in T \), let us define a function \( V_t : L_2(\mathcal{F}_t) \to R \) by

\[ V_t(f) = \sup_{K \in \mathcal{H}_t(f)} \left\{ \lim_{r \to +\infty} \inf_{s = t+1}^{r} \int_0^s v_t(k_{s-1}, k_s, \cdot) dP \right\} \quad \text{for } f \in L_2(\mathcal{F}_t). \]

Here, we should note that functions \( V_t \) are defined for a particular program \( K^* \), and they depend on the program.

Remark 3.3: It can be shown by definition of \( V_t \) that for each \( t \in T \),
In particular, if program $K^* = \{k_t^* | t \in T\}$ is weakly maximal, we can show that program $K^*$ is agreeable, i.e.,

$$V_t(k_t^*) = \int v_{t+1}(k_t^*, k_{t+1}^*, \cdot) dP + V_{t+1}(k_{t+1}^*) \quad \text{for all } t \in T.$$ 

For each $t \in T$, we define the effective domain of function $V_t$ by

$$\mathcal{Z}_t = \{f \in L_\infty(\mathcal{F}_t) | V_t(f) > -\infty\}.$$ 

Also, for each $t$, we define a set by

$$\mathcal{Y}_t = \{g | (f, g) \in \mathcal{Z}_t \text{ for some } f\}.$$ 

Furthermore, we assume the following condition for program $K^*$.

(C.2) $k^*_0 \in \text{int } \mathcal{Z}_0$ and $\text{int } (\mathcal{Y}_t \cap \mathcal{Z}_t) \neq \emptyset$ for all $t > 0$, where symbol "int" means the interior in the $||\cdot||_\infty$-topology for space $L_\infty(\mathcal{F}_t)$.

By assumption (A.1), we can easily show that $V_t$ is concave and $\mathcal{Z}_t$ is convex for each $t \in T$. Also, for each $t > 0$, define a map $\Psi_t : \mathcal{Z}_t \rightarrow \mathbb{R}$ by

$$\Psi_t(f, g) = \int_u u_t(f(\omega), g(\omega), \omega) dP.$$ 

Then, map $\Psi_t$ can be shown to be concave under assumption (A.1).

For each $t \in T$, let $L_\infty^*(\mathcal{F}_t)$ denote the dual space of $L_\infty(\mathcal{F}_t)$, i.e., the set of all continuous linear functions on $L_\infty(\mathcal{F}_t)$ to $\mathbb{R}$. For each $t \in T$ and $k \in L_\infty(\mathcal{F}_t)$, we define the set of subgradients of $V_t$ at $k$ by

$$\partial V_t(k) = \{\pi \in L_\infty^*(\mathcal{F}_t) | V_t(k) + \pi \cdot (f - k) \geq V_t(f) \quad \text{for all } f \in \mathcal{Z}_t\}.$$ 

Moreover, for each $t > 0$ and $(k, k') \in L_\infty(\mathcal{F}_{t-1}) \times L_\infty(\mathcal{F}_t)$, we define the set of subgradients of $\Psi_t$ at $(k, k')$ by

$$\partial \Psi_t(k, k') = \{\pi, \pi' \in L_\infty^*(\mathcal{F}_{t-1}) \times L_\infty^*(\mathcal{F}_t) | \Psi_t(k, k') + \pi \cdot (f - k) + \pi' \cdot (g - k') \geq \Psi_t(f, g) \quad \text{for all } (f, g) \in \mathcal{Z}_t\}.$$ 

Let us define prices of capital goods in program $K^*$.

**Definition 3.1:** We call $\{\pi_t | t \in T\}$ a price system supporting program $K^*$, if, for all $t \in T$, $\pi_t \in \partial V_t(k_t^*)$ and $(\pi_t, -\pi_{t+1}) \in \partial \Psi_{t+1}(k_t^*, k_{t+1}^*)$, i.e.,

1. $V_t(k_t^*) - \pi_t \cdot k_t^* \geq V_t(f) - \pi \cdot f$ for all $f \in \mathcal{Z}_t$. 

\[ V_t(f) \geq \int v_{t+1}(f, g, \cdot) dP + V_{t+1}(g) \quad \text{for all } (f, g) \in \mathcal{Z}_{t+1}. \]
Now we are ready to prove the existence of a price system supporting the weakly maximal program. First we shall prove the so-called induction lemma.

**Lemma 3.1:** Let $K^* = \{k^*_t | t \in T\}$ be a weakly maximal program satisfying conditions (C.1) and (C.2). Under assumptions (A.1) and (A.2), if $\pi_{t-1} \in \partial V_{t-1}(k^*_{t-1})$, then there exists $\pi_t \in \partial V_t(k^*_t)$ such that $(\pi_{t-1}, -\pi_t) \in \partial V_t(k^*_{t-1}, k^*_t)$.

**Proof:** Assume that $\pi_{t-1} \in \partial V_{t-1}(k^*_{t-1})$, and define a number $w_t$ by

$$w_t = u_t(k^*_{t-1}, k^*_t, \cdot) dP - \pi_{t-1} \cdot k^*_{t-1}$$

Also, define two sets,

$$A = \{(w, g) \in \mathbb{R} \times \mathcal{L}_w(\mathcal{F}_t) | \int w - \int u_t(f, g, \cdot) dP + \pi_{t-1} \cdot f > V_t(k^*_t) - \pi_t \cdot k^*_t \text{ for some } f \text{ with } (f, g) \in \mathcal{D}_t\},$$

and

$$B = \{(w, g) \in \mathbb{R} \times \mathcal{L}_w(\mathcal{F}_t) | V_t(g) \geq w\}.$$

Clearly, $(V_t(k^*_t), k^*_t) \in B$, and $(V_t(k^*_t), k^*_t) \in \partial A$. By assumption (A.1), these sets are convex. In addition, since int $\mathcal{L}_w(\mathcal{F}_t)$ by condition (C.2), set $B$ has non-empty interior.

Suppose $A \cap B \neq \emptyset$. Then there exists $(f, g) \in D_t$ such that

$$V_t(g) > w_t - \int u_t(f, g, \cdot) dP + \pi_{t-1} \cdot f.$$

By the definition of value function $V_t$, we have

$$V_{t-1}(f) - \pi_{t-1} \cdot f > V_{t-1}(k^*_{t-1}) - \pi_{t-1} \cdot k^*_{t-1},$$

which implies that $\pi_{t-1} \in \partial V_{t-1}(k^*_{t-1})$, a contradiction. Hence $A \cap B = \emptyset$.

By a separation theorem [Dunford & Schwartz (1964), Thm.V.2.8, p. 418], there exists a non-zero continuous linear function $(c, -\pi_t)$ on $\mathbb{R} \times \mathcal{L}_w(\mathcal{F}_t)$, i.e., a number $c$ and a function $\pi_t \in \mathcal{L}_w^*(\mathcal{F}_t)$ such that

$$c \cdot w - \pi_t \cdot g \geq c \cdot w' - \pi_t \cdot g' \text{ for all } (w, g) \in A \text{ and } (w', g') \in B.$$ 

This implies that

$$c[w_t - u_t(f, g, \cdot) dP + \pi_{t-1} \cdot f] - \pi_t \cdot g \geq c V_t(g') - \pi_t \cdot g' \text{ for all } (f, g) \in \mathcal{D}_t \text{ and } g' \in \mathcal{H}_t.$$ 

Suppose $c = 0$. (3.1) implies that $\pi_t \cdot (g' - g) \geq 0$ for all $(f, g) \in \mathcal{D}_t$ and $g' \in \mathcal{H}_t$. There-
fore, by condition (C.2), $\pi_t = 0$, which is a contradiction to $(c, \pi_t) \neq 0$. Hence, since $c \geq 0$ by the shapes of sets $A$ and $B$, we can assume that $c = 1$ without loss of generality.

Put $g' = k^*_t$ in (3.1). Then,

$\left[ u_t(k^*_{t-1}, k^*_t, \cdot) dP - \pi_{t-1} \cdot k^*_{t-1} + \pi_t \cdot k^*_t \right] \geq \left[ u_t(f, g, \cdot) dP - \pi_{t-1} \cdot f + \pi_t \cdot g \right]
$

for all $(f, g) \in \mathcal{D}_t$. This implies that $(\pi_{t-1}, -\pi_t) \in \partial \Psi_t(k^*_{t-1}, k^*_t)$.

Moreover, put $f = k^*_{t-1}$ and $g = k^*_t$ in (3.1). Then,

$V_t(k^*_t) - \pi_t \cdot k^*_t \geq V_t(g') - \pi_t \cdot g'$

for all $g' \in \mathcal{H}_t$,

which implies that $\pi_t \in \partial V_t(k^*_t)$.

Theorem 3.1: Let $K^* = \{k^*_t | t \in T\}$ be a program satisfying conditions (C.1) and (C.2). Under assumptions (A.1) and (A.2), if program $K^*$ is weakly maximal, there exists a price system supporting program $K^*$.

Proof: The theorem can be proved by an induction argument. Since $k_0^* \in \text{int} \mathcal{H}_0$ by condition (C.2), by a separation argument there exists $\pi_0 \in \partial V_0(k^*_0)$. Thus, by induction with respect to time $t$, Lemma 3.1 implies the existence of a price system $\{\pi_t | t \in T\}$ supporting program $K^*$.

For each $t > 0$ and $(k, k') \in \mathcal{L}^*(\mathcal{F}_{t-1}) \times \mathcal{L}^*(\mathcal{F}_t)$, we define the set of partial subgradients of $\Psi_t$ at $(k, k')$ by

$\partial \psi_t(k, k') = \{ \pi \in \mathcal{L}^*(\mathcal{F}_{t-1}) | (\pi, \pi') \in \partial \psi_t(k, k') \}$

Then, we have the following theorem, which is usually called “the envelope theorem.”

Theorem 3.2: Let $K^* = \{k^*_t | t \in T\}$ be a program satisfying conditions (C.1) and (C.2). Under assumptions (A.1) and (A.2), if program $K^*$ is weakly maximal, then $\partial V_t(k^*_t) \subset \partial \psi_{t+1}(k^*_t, k^*_{t+1})$ for all $t \in T$.

Proof: The theorem follows immediately from Lemma 3.1.

IV. Integrable Price Systems

For each $t \in T$, let $ba(\mathcal{F}_t)$ denote the set of all bounded finitely additive $m$-dimensional vector-valued measures on $\mathcal{F}_t$ absolutely continuous with respect to $P$. Also, let $\mathcal{L}_t(\mathcal{F}_t)$ denote the set of all integrable $\mathcal{F}_t$-measurable functions on $\Omega$ to $R^m$.

Remark 4.1: By a theorem [Dunford & Schwartz (1964), Thm.IV. 8.16, p. 296], $\mathcal{L}^*(\mathcal{F}_t)$ can be identified with $ba(\mathcal{F}_t)$, and for each $\pi \in \mathcal{L}^*(\mathcal{F}_t)$,
\[ \pi \cdot f = \int f \, d\pi \quad \text{for all } f \in \mathcal{L}_1(\mathcal{F}_t), \]

where \( \pi \) is also regarded as an element of \( ba(\mathcal{F}_t) \). In addition, if \( \pi \) is countably additive, then, by the Radon-Nikodym theorem [Dunford & Schwartz 1964, Thm.III.10.7, p. 181], there is a unique derivative of \( \pi \), say, \( p \in \mathcal{L}_1(\mathcal{F}_t) \) such that

\[ \int f \, d\pi = \int p \cdot f \, dP \quad \text{for all } f \in \mathcal{L}_1(\mathcal{F}_t). \]

Thus, \( \mathcal{L}_1(\mathcal{F}_t) \) can be regarded as a subset of \( ba(\mathcal{F}_t) \), or \( \mathcal{L}_*^1(\mathcal{F}_t) \).

Remark 4.2: If \( \pi \in ba(\mathcal{F}_t) \) is non-negative, then, by a theorem [Yosida & Hewitt (1952), Thm.1.23, p. 52], \( \pi \) can be uniquely decomposed into two parts, that is, there exist unique \( \pi_e \geq 0 \) and \( \pi_p \geq 0 \) in \( ba(\mathcal{F}_t) \) such that \( \pi_e \) is countably additive and \( \pi_p \) is purely finitely additive, and such that

\[ \pi = \pi_e + \pi_p. \]

Therefore, by the Radon-Nikodym theorem, there is a unique derivative of \( \pi_e \), say, \( p \in \mathcal{L}_1(\mathcal{F}_t) \) such that

\[ \int f \, d\pi_e = \int p \cdot f \, dP \quad \text{for all } f \in \mathcal{L}_1(\mathcal{F}_t). \]

Since \( \mathcal{L}_1(\mathcal{F}_t) \subset \mathcal{L}_*(\mathcal{F}_t) \), for \( p \in \mathcal{L}_1(\mathcal{F}_t) \) we can write \( p \in \partial V_i(k) \) if and only if \( V_i(k) + \int p \cdot (f - k) \, dP \geq V_i(f) \) for all \( f \in \mathcal{L}_1 \). Also, for \( p \in \mathcal{L}_1(\mathcal{F}_t) \) and \( p' \in \mathcal{L}_1(\mathcal{F}_{t+1}) \) we can write \( (p, -p) \in \partial W_{t+1}(k, k') \) if and only if \( \int u_{t+1}(k, k', \cdot) \, dP + \int p \cdot (f - k) \, dP - \int p' \cdot (g - k') \, dP \geq \int u_{t+1}(f, g, \cdot) \, dP \) for all \( (f, g) \in \mathcal{D}_{t+1}. \)

Now, we are interested in a price system \( \{p_t \mid t \in T\} \) such that \( p_t \in \mathcal{L}_1(\mathcal{F}_t) \) for all \( t \in T. \)

Definition 4.1: We call \( \{p_t \mid t \in T\} \) an \( \mathcal{L}_1 \)-price system supporting program \( K^* \), if, for all \( t \in T, p_t \in \mathcal{L}_1(\mathcal{F}_t), p_t \in \partial V_i(k^*), \) and \( (p_t, -p_{t+1}) \in \partial W_{t+1}(k^*_t, k^*_{t+1}), \) i.e.,

1. \[ V_i(k^*_t) - \int p_t \cdot k^*_t \, dP \geq V_i(f) - \int p_t \cdot f \, dP \quad \text{for all } f \in \mathcal{L}_1. \]
2. \[ \int u_{t+1}(k^*_t, k^*_{t+1}, \cdot) \, dP - \int p_t \cdot k^*_t \, dP + \int p_{t+1} \cdot k^*_{t+1} \, dP \geq \int u_{t+1}(f, g, \cdot) \, dP - \int p_t \cdot f \, dP + \int p_{t+1} \cdot g \, dP \quad \text{for all } (f, g) \in \mathcal{D}_{t+1}, \]

where \( V_i \) is the normalized value function for program \( K^* \).

In order to get an \( \mathcal{L}_1 \)-price system, the following lemma is useful.
Lemma 4.1: If \((\pi, -\pi') \in \partial F_{t+1}(k, k')\), \(\pi \geq 0\), and \(\pi' \geq 0\), then \((p, -p') \in \partial F_{t+1}(k, k')\), where \(p \in \mathcal{L}(\mathcal{F})\) and \(p' \in \mathcal{L}(\mathcal{F}_{t+1})\) are the derivatives of the countably additive parts \(\pi\) of \(\pi\) and \(\pi\) of \(\pi'\) respectively.

Proof: Since \(\pi \geq 0\) and \(\pi' \geq 0\), by Remark 4.2, \(\pi\) and \(\pi\) can be decomposed uniquely into a countable additive part and a purely finitely additive part. Namely, \(\pi\) is decomposed into \(\pi \in \text{ba}(\mathcal{F})\) and \(\pi \in \text{ba}(\mathcal{F})\), and \(\pi\) into \(\pi \in \text{ba}(\mathcal{F}_{t+1})\) and \(\pi \in \text{ba}(\mathcal{F}_{t+1})\). Also, let us denote the derivative of \(\pi\) by \(p\) and that of \(\pi\) by \(p\).

Moreover, by a theorem [Yosida & Hewitt (1952), Thm.1.22, p. 52], for \(\pi\) there is a sequence \(A_n \in \mathcal{F}\) such that \(A_n \subset A_{n+1}\) and \(\pi(A_n) = 0\) for all \(n\), and such that \(\lim_n P(A_n) = 1\). Since \(\pi\) is also a purely finitely additive measure defined on \(\mathcal{F}\), there is a sequence \(B_n \in \mathcal{F}\) such that \(B_n \subset B_{n+1}\) and \(\pi(B_n) = 0\) for all \(n\), and such that \(\lim_n P(B_n) = 1\). Define \(C_n = A_n \cap B_n\). Then, \(C_n \in \mathcal{F}\), \(C_n \subset C_{n+1}\), \(\pi(C_n) = \pi(B_n) = 0\) for all \(n\), and \(\lim_n P(C_n) = 1\).

Now, let \((f, g) \in \mathcal{D}_{t+1}\). For each \(n\), define functions \(f_n\) and \(g_n\) by

\[
(f_n(\omega), g_n(\omega)) = \begin{cases} (f(\omega), g(\omega)) & \text{for } \omega \in C_n \\ (k(\omega), k'(\omega)) & \text{otherwise,} \end{cases}
\]

Then, \((f_n, g_n) \in \mathcal{D}_{t+1}\). And, since \(\pi_n(C_n) = \pi_n'(C_n) = 0\), we have

\[
\pi \cdot (k - f_n) = \pi \cdot (k - f_n) + \pi \cdot (k - f_n)
\]

\[
= \left[p \cdot (k - f_n) dP + \int_{C_n} (k - f_n) d\pi_p\right]
\]

\[
= \int p \cdot k dP - \int p \cdot f_n dP
\]

and

\[
\pi' \cdot (k' - g_n) = \pi \cdot (k' - g_n) + \pi' \cdot (k' - g_n)
\]

\[
= \left[p' \cdot (k' - g_n) dP + \int_{C_n} (k' - g_n) d\pi_p\right]
\]

\[
= \int p' \cdot k' dP - \int p' \cdot g_n dP
\]

Thus, since \((\pi, -\pi') \in \partial F_{t+1}(k, k')\), we have

\[
\int u_{t+1}(k, k') dP + \int p \cdot (f_n - k) dP - \int p \cdot (g_n - k') dP \geq \int u_{t+1}(f_n, g_n, \cdot) dP
\]

for all \(n\). Since \(\lim_n P(C_n) = 1\), we have in the limit

\[
\int u_{t+1}(k, k', \cdot) dP + \int p \cdot (f - k) dP - \int p \cdot (g - k') dP \geq \int u_{t+1}(f, g, \cdot) dP.
\]

This completes the proof of the lemma.
In order to insure the non-negativity of prices we assume:

(A.3) (monotonicity) If \((x, y) \in D_t(\omega), x \leq x',\) and \(x \neq x',\) then \((x', y) \in D_t(\omega)\) and \(u_t(x, y, \omega) \leq u_t(x', y, \omega)\).

The above assumption is the monotonicity of utility functions with respect to initial capital stock at each period. Now, under this assumption, we are ready to prove:

**Theorem 4.1:** Let \(K^\ast_\omega = \{k^\ast_t | t \in T\}\) be a program satisfying conditions \((C.1)\) and \((C.2)\). Under assumptions \((A.1), (A.2),\) and \((A.3)\), if program \(K^\ast_\omega\) is weakly maximal, then there exists an \(\mathcal{L}_1\)-price system \(\{p_t | t \in T\}\) such that \((p_t, -p_{t+1}) \in \mathcal{P}_{t+1}(k^\ast_t, k^\ast_{t+1})\) for all \(t \in T\).

**Proof:** Theorem 3.1 implies the existence of a price system \(\{\pi_t | t \in T\}\) supporting program \(K^\ast_\omega\). Assumption \((A.3)\) implies that \(\pi_t \geq 0\) for all \(t \in T\). Therefore, this theorem follows from Lemma 4.1.

In order to prove the existence of an \(\mathcal{L}_1\)-price system supporting a program \(K^\ast_\omega\), we need to assume the interiority of the program. For each \(f \in \mathcal{L}_*(\mathcal{F}_{t-1})\), define

\[\mathcal{Y}_t(f) = \{g \in \mathcal{L}_*(\mathcal{F}_t) | (f, g) \in \mathcal{B}_t\}\].

At time \(t\), given \(k^\ast_{t-1}\), we choose \(k^\ast_t\) from set, \(\mathcal{Y}_t(k^\ast_{t-1})\). The following condition means that \(k^\ast_t\) is chosen in the interior of \(\mathcal{Y}_t(k^\ast_{t-1})\).

\((C.3)\) (interiority) \(k^\ast_t \in \text{int} \mathcal{Y}_t(k^\ast_{t-1})\) for all \(t > 0\).

For a weakly maximal program satisfying the above interiority condition, we can prove the existence of an \(\mathcal{L}_1\)-price system supporting it.

**Theorem 4.2:** Let \(K^\ast_\omega = \{k^\ast_t | t \in T\}\) be a program satisfying conditions \((C.1), (C.2),\) and \((C.3)\). Under assumptions \((A.1), (A.2),\) and \((A.3)\), if program \(K^\ast_\omega\) is weakly maximal, then there exists an \(\mathcal{L}_1\)-price system supporting program \(K^\ast_\omega\).

**Proof:** By Theorem 3.1 we have a price system \(\{\pi_t | t \in T\}\) supporting program \(K^\ast_\omega\), i.e., \(\pi_t \in \partial V_t(k^\ast_t)\) and \((\pi_t, -\pi_{t+1}) \in \partial W_{t+1}(k^\ast_t, k^\ast_{t+1})\) for all \(t \geq 0\). Assumption \((A.3)\) implies that \(\pi_t \geq 0\) for all \(t \in T\). Therefore, by Lemma 4.1, we have \(\{p_t | t \in T\}\), where \(p_t\) is the derivative of the countably additive part of \(\pi_t\) for each \(t\), such that \((p_t, -p_{t+1}) \in \partial W_{t+1}(k^\ast_t, k^\ast_{t+1})\) for all \(t \geq 0\). Therefore, it suffices only to prove that \(p_t \in \partial V_t(k^\ast_t)\) for all \(t \geq 0\).

Suppose that \(\pi_t\) were not countably additive, there would exist a sequence of sets \(A_n \in \mathcal{F}_t\) such that \(A_n \subset A_{n+1}\) and \(\pi_t(A_n) \leq \pi_t(\bigcup k A_k) - w\) for all \(n\), where \(w \in \mathbb{R}^\ast_+\), and \(w \neq 0\). Let \(B_n = A_n \cup (\Omega \setminus \bigcup k A_k)\). Then, \(\bigcup k B_k = \Omega\) and

\[(4.1) \quad \pi(B_n) \leq \pi_t(\Omega) - w\]

for all \(n\). Define \(f \in \mathcal{L}_*(\mathcal{F}_{t-1})\) by

\[(4.2) \quad f(\omega) = k^\ast_{t-1}(\omega) + \delta w,\]

where \(\delta \) is a small positive number such that \(\pi(B_n) \leq \pi_t(\Omega) - w\) for all \(n\).
where $\delta$ is a positive number. Also, for each $n$, define $g_n \in \mathcal{L}_n(\mathcal{F}_t)$ by

\begin{equation}
  g_n(\omega) = \begin{cases} 
  k^*_{t-1}(\omega) & \text{for } \omega \in B_n \\
  k^*_{t-1}(\omega) + \delta \pi_{t-1}(Q) & \text{otherwise}.
  \end{cases}
\end{equation}

Here, by condition (C.3), we can choose a sufficiently small $\delta$ such that $(k^*_{t-1}, g_n) \in \mathcal{D}_t$. Therefore, by assumption (A.3), $(f, g_n) \in \mathcal{D}_t$. Moreover, by assumption (A.3), \( \int u_t(k^*_{t-1}, k^*_t, \cdot) dP < \int u_t(f, k^*_t, \cdot) dP \). Therefore, since $\lim_n P(B_n) = 1$,

\[ \int u_t(k^*_{t-1}, k^*_t, \cdot) < \int u_t(f, g_n, \cdot) dP. \]

for all sufficiently large $n$. Since $(\pi_{t-1} - \pi_t) \in \partial u_t(k^*_{t-1}, k^*_t)$, we have, by (4.1), (4.2), and (4.3),

\begin{align*}
0 > & \int u_t(k^*_{t-1}, k^*_t, \cdot) dP - \int u_t(f, g_n, \cdot) dP \\
\geq & \pi_{t-1}(k^*_{t-1} - f) - \pi_t(f - g_n) \\
= & -\delta \pi_{t-1}(Q) \cdot w + \delta \pi_{t-1}(Q) \cdot \pi_t(Q \setminus B_n) \\
= & -\delta \pi_{t-1}(Q) \cdot w + \delta \pi_{t-1}(Q) \cdot (\pi_t(Q) - \pi_t(B_n)) \\
\geq & -\delta \pi_{t-1}(Q) \cdot w + \delta \pi_{t-1}(Q) \cdot w = 0,
\end{align*}

a contradiction. This proves the countable additivity of $\pi_t$. Thus, $p_t = \pi_t$ for all $t > 0$. Therefore, $p_t \in \partial V_t(k^*_t)$ for all $t > 0$.

In particular, we have shown that $p_t \in \partial V_t(k^*_t)$ and $(p_0, -p_1) \in \partial V_1(k^*_0, k^*_1)$. Let $(f, g) \in \mathcal{D}_t$. Then,

\[ V_t(k^*_1) + \int p_1 \cdot (g - k^*_1) dP \geq V_t(g) \]

and

\[ \int u_t(k^*_0, k^*_1, \cdot) dP + \int p_0 \cdot (f - k^*_0) dP - \int p_1 \cdot (g - k^*_1) dP \geq \int u_t(f, g, \cdot) dP. \]

Hence, by the above two inequalities,

\[ \int u_t(k^*_0, k^*_1, \cdot) dP + V_1(k^*_1) + \int p_0 \cdot (f - k^*_0) dP \geq \int u_t(f, g, \cdot) dP + V_1(g), \]

Thus, by definition of the value function $V_0$, we can conclude that

\[ V_0(k^*_0) + \int p_0 \cdot (f - k^*_0) dP \geq V_0(f). \]

This proves that $p_0 \in \partial V_0(k^*_0)$.
V. Complete Characterization of Weakly Maximal Programs

First we shall prove a fundamental theorem which shows a necessary and sufficient condition for weak maximality.

**Theorem 5.1:** Let $K^* = \{k^*_t | t \in T\}$ be a program satisfying conditions (C.1) and (C.2). Then, under assumptions (A.1) and (A.2), program $K^*$ is weakly maximal if and only if $\lim_{t \to \infty} V_t(k^*_t) = 0$ and there exists a price system $\{\pi_t | t \in T\}$ supporting program $K^*$.

**Proof:** (Necessity) Assume that program $K^*$ is weakly maximal. Then, by Theorem 3.1 we have a price system $\{\pi_t | t \in T\}$ supporting program $K^*$. Also, since program $K^*$ is weakly maximal, by definition of $V_t$, $V_t(k^*_t) = 0$ for all $t \in T$. Therefore, $\lim_{t \to \infty} V_t(k^*_t) = 0$.

(Sufficiency) Assume that $K^*$ is a program satisfying conditions (C.1) and (C.2), and that $\lim_{t \to \infty} V_t(k^*_t) = 0$ and there exists a price system $\{\pi_t | t \in T\}$ supporting program $K^*$. First we shall show that program $K^*$ is agreeable, i.e.,

\[(5.1) \quad V_0(k^*_0) = \sum_{s=1}^{t} \int v_s(k^*_{s-1}, k^*_s, \cdot) dP + V_t(k^*_t) \quad \text{for all } t > 0.\]

where $v_s$'s are the normalized utility functions for program $K^*$.

Suppose that (5.1) were not true. Then, by definition of $V_0$, there is $t' > 0$ such that

\[\sum_{s=1}^{t'} \int v_s(k^*_{s-1}, k^*_s, \cdot) dP + V_{t'}(k^*_{t'}) > \sum_{s=1}^{t} \int v_s(k^*_{s-1}, k^*_s, \cdot) dP + V_t(k^*_t).\]

Therefore, again by definition of $V_0$, there exists $K \subseteq \mathcal{K}_0(k^*_0)$, $\varepsilon > 0$, and $t'' > t'$ such that

\[(5.2) \quad \sum_{s=1}^{t} \int v_s(k^*_{s-1}, k^*_s, \cdot) dP + V_{t}(k^*_t) > \sum_{s=1}^{t'} \int v_s(k^*_{s-1}, k^*_s, \cdot) dP + V_t(k^*_t) + \varepsilon \quad \text{for all } t > t''.\]

On the other hand, since $\{\pi_t | t \in T\}$ is a price system supporting program $K^*$,

\[V_t(k^*_t) - \pi_t \cdot k^*_t \geq V_t(k_t) - \pi_t \cdot k_t\]

and

\[\int u_t(k^*_{t-1}, k^*_t, \cdot) dP - \pi_{t-1} \cdot k^*_{t-1} + \pi_t \cdot k^*_t \geq \int u_t(k_{t-1}, k_t, \cdot) dP - \pi_{t-1} \cdot k_{t-1} + \pi_t \cdot k_t\]

for all $t > 0$. Since $k_0 = k^*_0$, these inequalities imply that

\[\sum_{s=1}^{t} \int v_s(k^*_{s-1}, k^*_s, \cdot) dP + V_t(k^*_t) \leq \sum_{s=1}^{t} \int v_s(k^*_{s-1}, k^*_s, \cdot) dP + V_t(k_t)\]

for all $t > 0$. This contradicts (5.2). Thus, (5.1) has been proved.
Now, by (5.1) and by definition of functions $v_t$'s, $V_0(k^*_0) = V_t(k^*_0)$ for all $t > 0$. Therefore, since $\lim_{t \to \infty} V_t(k^*_t) = 0$, we can conclude that $V_0(k^*_0) = 0$. Hence, by definition of $v_t$'s,

$$V_0(k^*_0) = \sum_{s=1}^{+\infty} v_t(k^*_{t-1}, k^*_t, \cdot)dP.$$  

By definition of $V_0$, this implies the weak maximality of program $K^*$. 

Now we can prove a useful theorem in the case where the sum of expected utilities is finite. We assume in addition the following:

(A.4) For each $t$, $(x, y) \in D_t(\omega)$ implies $x \geq 0$.

(A.5) For each $t$ and $\omega$, $(0, 0) \in D_t(\omega)$ and $u_t(0, 0, \omega) \geq 0$.

Assumption (A.4) means that capital stock must be non-negative. And, assumption (A.5) means possibility of inaction, namely that capital stock can be zero.

**Theorem 5.2:** Let $K^* = \{k^*_t | t \in T\}$ be a program satisfying conditions (C.1) and (C.2), and assume that $\sum_{t=1}^{+\infty} u_t(k^*_{t-1}, k^*_t, \cdot)dP$ exists and is finite. Then, under assumptions (A.1), (A.2), (A.3), (A.4), and (A.5), program $K^*$ is weakly maximal if and only if there exists a price system $\{\pi_t | t \in T\}$ satisfying the following conditions:

1. For each $t > 0$,

$$\int u_t(k^*_{t-1}, k^*_t, \cdot)dP - \pi_{t-1} \cdot k^*_{t-1} + \pi_t \cdot k^*_t \geq \int u_t(f, g_t, \cdot)dP - \pi_{t-1} \cdot f + \pi_t \cdot g$$

for all $(f, g) \in \mathcal{D}_t$.

2. $\lim_{t \to +\infty} \pi_t \cdot k^*_t = 0$.

**Proof:** (Necessity) Assume that program $K^*$ is weakly maximal. Then, by Theorem 3.1 we have a price system $\{\pi_t | t \in T\}$ supporting program $K^*$. Therefore, for each $t \in T$, $V_t(k^*_t) - \pi_t \cdot k^*_t \geq V_t(f) - \pi_t \cdot f$ for all $f \in \mathcal{L}(\mathcal{F}_t)$, where $V_t$ is the normalized value function for program $K^*$. Hence, by putting $f = 0$, we have

$$V_t(k^*_t) - V_t(0) \geq \pi_t \cdot k^*_t \quad \text{for all } t.$$  

In addition, by definition of $V_t$ and assumption (A.5),

$$V_t(0) \geq \int_{s=t+1}^{+\infty} u_s(0, 0, \cdot)dP \geq -\int_{s=t+1}^{+\infty} u_s(k^*_{s-1}, k^*_s, \cdot)dP$$

for all $t > 0$, where $v_s$'s are the normalized utility functions for program $K^*$. Thus, by the above two inequalities, we have
\[ V_t(k^*; k_t) + \sum_{s=t+1}^{+\infty} \int u_t(k^*_{s-1}, k^*_s, \cdot) \, dP \geq \pi_t \cdot k^*_s \quad \text{for all } t > 0. \]

By Theorem 5.1, \[ \lim_{t \to +\infty} V_t(k^*_t) = 0. \] Also, since \[ \sum_{s=t+1}^{+\infty} \int u_t(k^*_{s-1}, k^*_s, \cdot) \, dP \] is finite,

\[ \lim_{t \to +\infty} \sum_{s=t+1}^{+\infty} \int u_t(k^*_{s-1}, k^*_s, \cdot) \, dP = 0. \]

Hence, the above inequality implies that \( \lim \sup \pi_t \cdot k^*_t \leq 0 \). On the other hand, (A.4) implies that \( k^*_t \geq 0 \), and (A.3) implies that \( \pi_t \geq 0 \). Hence, \( \pi_t \cdot k^*_t \geq 0 \) for all \( t > 0 \). Therefore, we can conclude that \( \lim_{t \to +\infty} \pi_t \cdot k^*_t = 0 \).

(Sufficiency): Let \( K^* = \{k^*_t \mid t \in T\} \) be a program satisfying conditions (C.1) and (C.2), and assume that there exists a price system \( \{\pi_t \mid t \in T\} \) satisfying conditions (1) and (2) of this theorem.

Now, let \( K = \{k_t \mid t \in T\} \) be a program such that \( k_0 = k^*_0 \). Since \( \{\pi_t \mid t \in T\} \) satisfies condition (1) of this theorem,

\[ \int u_t(k^*_{t-1}, k^*_t, \cdot) \, dP + \pi_{t-1} \cdot (k_{t-1} - k^*_{t-1}) - \pi_t \cdot (k_t - k^*_t) \geq \int u_t(k_{t-1}, k_t, \cdot) \, dP \]

for all \( t > 0 \). Since \( k_0 = k^*_0 \), by summing up we have

\[ \pi_t \cdot k^*_t - \pi_t \cdot k_t \geq \sum_{s=1}^{t} \int u_t(k_{s-1}, k_s, \cdot) \, dP - \sum_{s=1}^{t} \int u_t(k^*_{s-1}, k^*_s, \cdot) \, dP \]

for all \( t > 0 \). (A.3) and (A.4) imply that \( \pi_t \cdot k_t \geq 0 \). Hence, the above inequality and condition (2) of this theorem imply that program \( K \) does not overtake program \( K^* \). Namely, program \( K^* \) is weakly maximal.
