Analyzing the diverse impact of digital use on the job quality
Comparing work organization and job satisfaction in Japan and France*

Sébastien Lechevalier[†] and Malo Mofakhami[‡]

April 2023

Abstract: What is the impact of digitalization on job quality? While the literature has mainly focused on the effects on performance and volume of employment, it has relatively neglected the qualitative issues, including when the existence of a digital divide is discussed. This paper tries to fill the gap through a comparative analysis of the diverse impacts of digital use on work organization and job satisfaction in Japan and France, two comparable countries with distinctive features regarding both digital use and work. To do so, we propose a simplified mediation model that synthesizes the different relations at stake. Our results can be summarized as follows. First, we did not find overall substantial differences between the two countries regarding the impact of digital use on job quality. Second, we find no direct effect of digital use on job satisfaction. However, digital use is correlated to some work organization practices, through which it has positive mediated effects. Third, the most massive source of the digital divide is, in both countries, related to the absence of digital skills. We also find other sources of individual heterogeneity, for which the patterns are different between the two countries.

Keywords: *Digital use, Job quality, Job satisfaction, Work organization, New technology adoption, Comparative analysis.*

1 Introduction

Digitalization has attracted a lot of attention because of its capacity to transform the competitive environment of firms, and increase their performance, but also to create and destroy many jobs (Acemoglu and Restrepo, 2019; OECD, 2019; McAfee and Brynjolfsson, 2017; Frey and Osborne, 2017; Elliott, 2017). In this context, few studies focus on more qualitative dimensions of the impact of increasing digital use on jobs and employment (Mofakhami, 2021; Bolli and Pusterla, 2022; Eurofound, 2020; Martin and Hauret, 2020). Moreover, although the risk of a digital divide has been emphasized, the analysis of the diverse impact of digital use within one country and between countries is still relatively limited (Martin and Hauret, 2020).

The major goal of this paper is to fill the gap and investigate the qualitative impact of digital use on job quality, which is decomposed into two major components, work organization practices and subjective job satisfaction (Brown et al, 2012; Clark, 2015; Martin and Hauret, 2020). A major problem that we face is that there is no unified model: the effect of new technology adoption on working conditions and job satisfaction is addressed by several pieces of literature, but none of them provides a clear and comprehensive theoretical framework, from which we can derive unambiguous hypotheses. The challenge is to study several simultaneous relations, at different levels of analysis, and with direct and indirect effects (mediation factors). To be able to test the relationships between digital use and job quality we introduce a simplified mediation model that synthesizes the different relations of interest.

In this context, our empirical strategy has two characteristics. The first one is to investigate jointly two different but related questions. First, we study the impact of digitalization on work organization (WO). The previous literature confirms the correlation but the causality is unclear and may be in two directions (Askenazy and Caroli, 2010; Martin and Omrani, 2015). We adopt a tasks-oriented point of view arguing that technology use and work organizations are co-determined, and moderated by institutional context (Piva and Vivarelli, 2018; Fonseca et al., 2018; Mofakhami, 2021). To characterize work organization at the firm level, we extend Lorenz et al. (2016)'s

framework by considering four broad categories of WO: autonomy and flexibility; learning activities; training; cooperation.

The second question we address is about the role played by digitalization in job satisfaction, and how it can influence it. Our expected contribution is to look at the ways the effects of digital use on job satisfaction are mediated by WO characteristics while controlling for other work-related characteristics and employees' specific factors that determine job satisfaction (working environment and employees' characteristics).

One originality of our empirical strategy is to look at the diverse impacts of digitalization on work organization and job satisfaction through a comparison between France and Japan. In the absence of a general model, there are some obvious benefits of a cross-countries comparison to identify some general patterns and mechanisms. Previous work stresses the major role played by institutional settings in the adoption of new technology but also the effects on employment (Calvino and Virgillito, 2017; Dosi and Mohnen, 2019; Kolade and Owoseni, 2022). From this perspective, these two countries are both relatively similar (e.g. spread of digital use; no polar cases in terms of job satisfaction) and different (e.g. corporate culture, work organization). We may thus assume that the impact of digitalization will be different between the two countries.

To proceed with this comparison, we mobilise the PIAAC 2013 survey (with data collected in 2011 and 2012). This old survey does not allow us to study the most recent evolutions. However, we can adopt a historical perspective on digital use in its basic components (email, Internet, Word, and spreadsheet use) at a time they were already very spread but unevenly across sectors and firms. In doing so, we can capture its differentiated impact on job quality and job satisfaction as subjectively assessed by workers. It is indeed worth emphasizing that the effects of a given technology on job satisfaction are evolving over time (e.g. initial stress or excitement related to a new technology that may vanish after some time, especially after some adjustment).

Our results can be summarized as follows. First, surprisingly, we did not find overall substantial differences between the two countries regarding the impact of digital use on work organization practices and job satisfaction. Second, we find no direct effect

of digital use on job satisfaction. However, digital use is associated with work organization forms, through which it has positive indirect effects on job satisfaction. Third, the absence of direct effects of digital use on job satisfaction can be decomposed into two indirect effects, a negative one (techno-strain) and a positive one, for those who have the right digital skills. This mechanism is a source of inequalities within each country. Moreover, and this is our fourth major result, there are also other sources of individual heterogeneity, for which the patterns are different between the two countries. It means that the similar patterns between Japan and France that have been found in our general model should be relativized when one looks at within countries differences (among workers with different characteristics).

In the rest of the paper, we proceed as follows. The next section summarizes some stylized facts and findings from the previous literature while emphasizing the absence of a general model that summarizes the effect of digital use on job quality. In section 3, we introduce our dataset and our empirical methodology. Section 4 presents our results. A final section concludes.

2 Digitalization: literature survey and stylized facts

2.1 Digitalization and job quality

The relationship between digitalization and employment is a major topic, as digital technologies have become widespread at work. Digital technologies are leading the current technological cycle (*Digital Revolution*), and all the productive system is transformed by the so-called “*Information and communication technologies (ICT)*” (Mcafee and Brynjolfsson, 2017). However, the interaction between digital use and employment is not so easy to define. As documented by rich literature, digital technology can be considered both a product innovation and a process innovation depending on the case (Duhautois et al., 2020; Mofakhami, 2019; Calvino and Virgillito, 2017). Product innovation is labour-friendly in terms of job creation at the firm level but in terms of the impact of working conditions and job satisfaction, process-oriented technology plays the central role.

In this regard, the “tasks model” brings some interesting insights, as it decomposes the different cases of how technology can change the tasks (Piva and Vivarelli, 2018;

Acemoglu and Restrepo, 2019). Some tasks are replaced by technology but others are created. So, the content of the work changes: even if digital diffusion in the economy also destroys jobs, it creates others and brings new tasks. The effects of new technologies and especially digital ones on working conditions and job satisfaction depend on the types of new tasks compared to those replaced. For sure, we can make the hypothesis that digital adoption is not a homogenous phenomenon among workers. The effects rely on occupations but also institutional settings.

Understanding how technologies are adopted and their impact implies understanding the very nature of the firm. Production is a set of tasks executed by humans and technologies (labour and capital) but within an organization which has some properties. A large literature adopts institutional and evolutionary perspectives to understand the technology - employment nexus (Becker et al., 2005; Dosi and Nelson, 2010; Nelson and Winter, 1982). The firm is part of a specific context, by its past and its institutional environment (norms, regulations, networks, etc.); a firm has routines which can be defined by a set of organizational practices and collective capacity. From this perspective, the firm is an organization based on more or less rigid routines, which are disrupted by the diffusion and adoption of technologies, knowledge and know-how. The qualifier "evolutionary" emphasizes the constant disruption that organizations face, and that leads to their evolution. Thus, a framework that blends evolutionary economics approaches and works task designs seems particularly well suited to conceptualising the effects of digital use on working and employment conditions (Mofakhami, 2019; 2021). From this perspective, the context determines the feasible combination of tasks between labour and technology. We then can assume the relationship between digital adoption and working satisfaction is not homogenous over countries, regions, sectors, and firms.

Some previous empirical works focus on the effect of digital use on working conditions and job satisfaction but they found diverging results. Based on the above theoretical framework, we can understand and articulate this literature: it is a question of noting the recurrences specific to digital technologies but also of identifying the sources of heterogeneity.

The empirical studies dedicated to the effect of digital use on job quality and working conditions document two opposing sets of relationships. On the one hand, a first

set of works supports the view of a so-called *helpful relation* (Bolli and Pusterla, 2022; Castellacci and Viñas-Bardolet, 2019; Martin and Omrani, 2015). Digital technologies mainly replace routine and repetitive tasks, fostering new and diverse activities. Increasing information access and adaptability also increases autonomy, saves time, and facilitates communication and thus cooperation (Castellacci and Viñas-Bardolet, 2019).

On the other hand, digital tools can contribute to the emergence of working conditions issues (Green et al. 2021; Berg-Beckhoff et al., 2017; Salanova et al., 2014; Askenazy and Caroli, 2010; Green, 2006). Digital technologies may increase anxiety, scepticism, and fatigue because they bring novelty and reorganization of work. It may also decrease working time quality, by blurring the frontiers between working, private, and rest times, and by exporting work stress outside the workplace. This second set of negative effects can be qualified as a “techno-strain” relation. Furthermore, digital technologies can also be associated with the growing use of external flexibility, by encouraging more spatial flexible work (Valenduc and Vendramin, 2017)

Then empirically as well as theoretically digital technology have unclear relationships with satisfaction (Dengler et al., 2022; Charalampous et al., 2019; Eurofound, 2020). The effect of digital use is thus ambiguous. The dimensions of the working conditions affected can be various: some seem to be improved (more autonomy and reduction of physical and repetitive tasks) but others are deteriorated (stress, blurring the work-life balance frontier, and increasing work intensity). Martin and Hauret (2020) provide a very exhaustive and complete literature review on the relationship between digital use and job satisfaction. They argue that, so far, empirical works led to substantially different results. They stress the need to further analysis taking into account diverse dimensions of job quality, the institutional context as well as the measure of digital use. The multidimensional aspect of job quality, different types of digital and technology use and the importance of the institutional context make the analysis particularly difficult.

Nevertheless, a shared characteristic of this diverse literature – either focusing on the techno-strain relation or the helpful one - is the role played by changes in work organization practices. New technologies impact working conditions not by themselves but through the reorganization of tasks and jobs (Bolli and Pusterla, 2022; Sarti et al.,

2020; Castellacci and Viñas-Bardolet, 2019). From this perspective, digital technologies can produce direct effects but also indirect effects through changes in organizational practices. Technology *per se* does not make people more productive or happier; these are the induced changes that matter.

A last characteristic of digital technology is its evolutionary effect (Mofakhami, 2021). Digital technologies are considered new and innovative but over time, after having been introduced and incorporated into the work organization of the firm, they are not new anymore. Also, the adoption of digital technologies induces two effects, which should be differentiated: a perturbative effect due to novelty (changes in organizational practices) and a technological effect *per se*. Over time, the first effect tends to disappear as soon as the workers have adapted to the technology and become used to it, while the second effect will persist. This dynamic is a key characteristic of the impact of technology on work and labor. It is then often difficult to distinguish effects from the technology by itself from the perturbative effect of the novelty. For instance, anxiety about novelty or lack of competence due to new digital technologies can disappear over time.

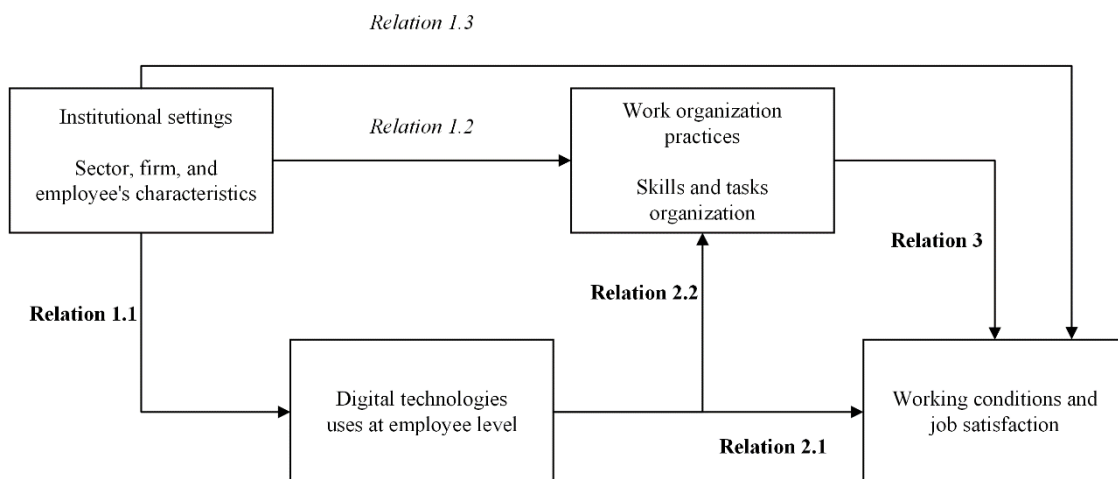

2.2 *A synthetic theoretical model*

The theoretical and empirical literature does not provide a clear comprehensive theoretical framework, from which we can derive unambiguous hypotheses. The challenge lies in the nested relationships between digital technology use, work organization practices and working conditions, and satisfaction. There are several simultaneous relations, at different levels of analysis, and with direct and indirect effects (mediation factors). The major difficulty comes from the relationship between organizational practices and digital use. Identifying which one causes the other is difficult, some research support that innovative workplaces and High-performance work system (HPWS) or Innovative workplaces (OECD, 2010; Boxall and Macky, 2009) are needed to foster the adoption of new technologies, but other studies claim that adoption of new technologies is a way to change the work and task organization. Probably they are partly codetermined. Beyond this major difficulty in our conceptual framework, the rest of the relations that are studied are more robust and clearer. For instance, institutional setting (macro- and meso-level), firm and employees' socio-economics characteristics determine

digital technology use and job satisfaction, as well as digital use and work organisation determine job satisfaction.

Based on this literature review we adopt an operational synthetic model derived from the “evolutionary tasks-based approach” (Lorenz and Valeyre, 2005; Becker et al., 2005; Eurofound, 2017b; Mofakhami, 2021). Figure 1 presents the framework we adopt to analyse the effect of digital use at the employee level on job satisfaction.

Figure 1: Conceptual framework of digital use and satisfaction based on an evolutionary tasks-based approach

Based on this scheme, our empirical analysis will investigate more particularly, in France and Japan, the determinants of digital use (Relation 1.1), the direct relation of digital use on job satisfaction (Relation 2.2), and the mediated relation of digital use on job satisfaction through work organization practices (Relation 2.1 combined with Relation 3). The following section discusses this conceptual framework about institutional differences in France and Japan and presents empirical articles addressing this topic in both countries.

2.3 Digitalization, job satisfaction, work organization, and labour market institutions: Comparing France and Japan

To be able to formulate some hypotheses on the possible impact of digital use on job quality in France and Japan, we briefly review the literature on work and labour in these

two countries. We avoid stereotypical images and take into account the fact that both countries have experienced substantial transformations of the respective labour markets and work organization patterns during the last three decades.

Regarding their labour markets, both countries have been considered as characterized by a dual structure and ‘rigid’ institutions (Thomas Le Barbanchon, 2013; Watanabe, 2018; Lechevalier, 2014). However, the lines of cleavage and the composition of the two tiers are different. Duality is more about male vs female workers or manufacturing vs. services in Japan (Kambayashi and Kato, 2017; Kambayashi and Kato, 2016), while it is more based on the level of occupation in France (Askenazy, 2018; Green et al., 2013).

However, this dual structure has evolved. By the end of the 1990s, France had experienced a polarization between white-collar and blue-collar workers, reinforced by skilled-biased technological change (Greenan, 2003). By contrast, until the mid-1990s, Japan was characterized by a “white collarization” of blue-collar workers (Koike, 1988), thus less polarization among workers (Lechevalier, 2014). During the 2000s, France experienced a flexibilization of the labor market, mainly concentrated on low-skilled workers and service sectors (Askenazy, 2018). To some extent, a similar trend can be observed in Japan, but in a more limited manner and mainly through the increase of the share of non-regular workers, which are partly replacing independent workers (Kambayashi & Kato, 2016).

In terms of human resource management (HRM) practices (and thus in terms of work organization), the contrast between the two countries has been much emphasized, although we should recognize some diversity within each country, between sectors and within sectors (Dosi et al., 2010). To summarize, HRM practices in Japan have been characterized by lean management practices where teamwork is efficient, cooperation is key, autonomy is high, and training level is high (Ikenaga and Kambayashi, 2016; Kambayashi and Kato, 2016; Morris et al., 2021; Takeuchi et al., 2007). By contrast, during the 2000s, several studies showed that, even if France had protective labor market institutions (at the macro-level), the quality of HRM was poor, by comparison to similar developed European countries: the training level was low, the management was

conflictual and could be characterized as a *discretionary hierarchized organization* (OECD, 2010; Eurofound, 2020; Eurofound, 2017b; Davoine et al., 2008).

In addition, the rotation of tasks and job content, which was central in Japan, did not exist in France (except for high-skilled workers and civil servants). Although investment in training has dramatically decreased in Japan (Yokoyama et al., 2019), it is still much higher than in France and less polarized (see Section 3).

Lastly, although, France and Japan are no polar cases from the viewpoint of job satisfaction, recent data show a higher level of job satisfaction for French workers¹. Besides the differences in the average level of job satisfaction, more importantly, the literature emphasizes different determinants. Job quality and job satisfaction in France are strongly related to occupation with polarized situations in terms of quality of working conditions (Askenazy and Caroli, 2010; Askenazy, 2018; Green et al., 2013). On the contrary, in Japan, the working conditions and organization seem to be relatively more homogeneous within firms (Takeuchi et al., 2007; Magnier-Watanabe et al., 2019). Moreover, in Japan, cooperation and collective achievement seem to be also stronger drivers of job satisfaction, while in France, standardized tasks reduce job satisfaction (Takeuchi et al., 2007; Sasaki et al., 2019; Magnier-Watanabe et al., 2019). However, in both countries, studies show that autonomy and time flexibility are considered keys to improving job satisfaction at work, whilst long hours deteriorate job satisfaction (Fujimoto et al., 2016; Eurofound, 2017a; Kuroda and Yamamoto, 2016; Lott, 2015).

Based on the previous conceptual framework we presented and this comparison between France and Japan from the perspective of labour market dynamics, human resource management, and determinant of job satisfaction, we can derive the following hypotheses that our empirical investigation will allow us to test²:

¹ Some studies based on the 2005 International Social Survey Program showed that Japanese and French workers have really similar level of job satisfaction, but more recent data from OECD PIAAC data show that French workers experienced higher level of job satisfaction than Japanese one (see section 3).

² We leave aside the following hypothesis, which is recognized as important by the literature but that we are unable to test with our data: digital use can increase the work pressure and working time, and thus may decrease job satisfaction in both countries through this channel.

1. Digital use may improve autonomy, cooperation and learning at work and, thus increase job satisfaction for both countries;
2. Work organization practices appear more heterogeneous in France than in Japan, while the digital intensity is higher. Thus, the effects of digital are expected to be stronger and more polarized in the French case than in the Japanese one;
3. Finally, both countries are characterized by dual labour markets but with different lines of cleavage, so we should find heterogeneous effects by sectors and occupations that are themselves different in each country.

Before moving to the empirical results that will confirm or not these hypotheses, we present the data used and the empirical strategy adopted in the next section.

3 Data and empirical strategy

3.1 Data

In this paper, we mobilize data from the 2013 edition of the PIAAC survey (*Programme for the International Assessment of Adult Competencies* or *Survey of Adult Skills*), which is a high-quality international cross-section database provided by the OECD, and which covers the years 2011 and 2012 for Japan and France³. It covers skill and competencies topics at the individual level from a comparative perspective. It is a major source to get information on skills, tasks, and lifelong education and training both formal and informal. The survey is conducted by the OECD in all the countries of the organization and beyond (around 40 countries). It includes data on about 5,000 representative adults aged 16 to 65 in each country. The survey identifies individuals who are employed and addressed questions about digital use (adoption and frequency of use for several computer usages), job satisfaction but also most of the key sociodemographic characteristics.

For the sake of our analysis, we focus on the Japanese and French employees and we obtain a total sample of 6,977 employees (3,620 French and 3,357 Japanese)⁴. The measure of digital use is an index built from several questions about the adoption and frequency of use of email, internet, spreadsheet, and Word (or similar software). The

³ For more information on PIAAC, the following dedicated website is very useful: <https://www.oecd.org/skills/piaac/>

⁴We exclude all the self-employed workers in order to focus on employees only.

digital use that we consider in this paper does then correspond to basic tasks, which, however, were not yet fully spread in 2010, depending on the countries, the sectors, the firms, and the specific occupation of employees.

The survey asks a question about the level of job satisfaction, an ordinal variable in five items (from *extremely satisfied* to *extremely dissatisfied*). This variable is used as our outcome variable (after being transformed into an index: see Table A1 in Appendix). To capture some characteristics of work organization practices, several indexes are derived from combinations of questions that ask the organization of the tasks at the individual level. In line with our conceptual framework and the literature on work organization practices - in particular, various contributions by Lorenz (e.g., Lorenz et al., 2015) -, we build three indexes that capture characteristics of work organization practices:

- (1) the level of learning at work (captured by variables indicating how much employees learn from the task performed, which is considered a proxy of low-level routinized tasks);
- (2) the autonomy and flexibility (which refer to employees' involvement in the design of work activity and their responsibility for planning and carrying out their tasks);
- (3) the degree of cooperation at work (which is captured through the three following variables: how much employees share information with co-workers, how much they learn from co-workers, and how much time they spend cooperating with co-workers).

Moreover, we add a dummy variable (4) that indicates if the employee participated or not, in (formal and non-formal) training activities during the 12 previous months.

The details of the original variables and the method of construction are available in table A1 in the appendix. All the ordinal variables are transformed in indexes from 0 (the lowest category) to 1 (the highest category). The choice of using indexes instead of ordinal variables is motivated by the literature on job quality (Eurofound, 2017a; Green et al., 2013; Eurofound, 2020; Mofakhami, 2021). It enables us to keep the maximum variance, conversely to use dummies, and it also standardizes the variance of the variables. Then, the resulting indexes are aggregated (in building average measures) by similar themes after having checked that they correlate to gather and reflect the same dimension (Alpha-Cronbach tests are used). The combination of indexes allows us to capture convergent social phenomena more robustly than through only one variable.

Moreover, the PIAAC dataset provides numerous socio-economic variables that we will use for our analysis. From the initial variables, we select the following socio-economic variables: size of the workplace, hourly wage (in PPP), occupation, sector of the workplace (industry and public or private sector), type of contract, education level, age, gender, structure of the household (in couple, having child, number of people in the household), health level, and a proxy of the cultural activity (number of book at home).

The survey provides also a subjective variable that indicates if the workers who use digital at work *think* they have a sufficient level of skills. We consider here this subjective variable as a proxy for the lack of skills related to digital use. We will use it in the last part of the analysis dedicated to regression by sub-categories of workers

Descriptive statistics present a first picture of the adoption of digital use in both countries in 2011-2012 (see Table 1). One can notice two major differences. First, the average level of adoption (independently from the frequency of use) is higher in Japan than in France: 73.5% of the Japanese workers report having experience with computer or ICT tools at work against 67.1% for the French workers. However, in terms of frequency, the index of digital use is equivalent in France and Japan (0.43). When considering only those workers who declare computer experience, the gap is in favour of French workers (+6.7%). These statistics suggest a slightly divergent pattern between both countries. In Japan, the ICT tools at work were more widespread in the early 2010s than in France, but the usage of ICT was more intense for French workers, who were concerned by digital use.

In terms of Job satisfaction (see Table 1), we also observe some differences between the workers of the two countries. The French workers are on average more satisfied at work than Japanese ones: satisfaction is 8.4% higher for French workers and it confirms the previous works showing a relatively low level of job satisfaction in Japan in comparison to other OECD countries (see section 2).

Table 1: Digital use and job satisfaction in France and Japan

<i>Standardized from 0-1 (mean, confidence interval)</i>	Index of digital use	Index of satisfaction
France	0.43	0.80
<i>CI at 95%</i>	<i>[0.42 ; 0.44]</i>	<i>[0.79 ; 0.8]</i>
Japan	0.43	0.71
<i>CI at 95%</i>	<i>[0.42 ; 0.45]</i>	<i>[0.71 ; 0.72]</i>
Total	0.44	0.76

Source: PIAAC data – 2011. French (4,095) and Japanese (3,717) employees. Statistics with corrected by sample weight.

The work organization practices also differ (Table 2). Japanese workers are more likely autonomous and flexible (34% more) and they get more training than French workers (+8.7%). Conversely, French workers learn more at work (less routinized tasks, +8.8%). The level of cooperation at work is close in both countries.

Table 2: Work organization practices and tasks uses in France and Japan

<i>Standardized from 0-1 (mean, confidence interval)</i>	Autonomy and flexibility index (score)	Learning index (score)	Cooperation index (score)	Participated in formal or non-formal training (dummy)
France (mean)	0.46	0.62	0.71	0.46
<i>CI at 95%</i>	<i>[0.45 ; 0.47]</i>	<i>[0.61 ; 0.63]</i>	<i>[0.70 ; 0.72]</i>	<i>[0.44 ; 0.48]</i>
Japan (mean)	0.62	0.57	0.72	0.50
<i>CI at 95%</i>	<i>[0.61 ; 0.63]</i>	<i>[0.56 ; 0.58]</i>	<i>[0.71 ; 0.73]</i>	<i>[0.48 ; 0.52]</i>
Total (mean)	0.56	0.59	0.69	0.48

Source: PIAAC data – 2011. French (4,095) and Japanese (3,717) employees. Statistics with corrected by sample weight.

Nevertheless, all these differences can be due to institutional differences such as labour and industrial relations, but they can also be explained by differences in industry and workforce structures. Table 3 confirms that there are substantial differences between the two countries from this perspective. The Japanese workforce is less skilled in terms of occupation than the French. Another distinction is the education level: the Japanese workforce is less polarized, with most of the workers with Upper Secondary and Tertiary

bachelor's degrees, while French workers are more likely Lower Secondary or Upper Tertiary (Master's degree). Finally, these differences reflect also two patterns of economic sector structure. The Japanese economy is more manufactured industry oriented while the French economy is mainly led by services activities. To go further, it is thus necessary to lead multivariate analysis and compare workers with controlled characteristics.

Table 3: Socio-economic characteristics of employees in France and Japan

in %	France	Japan	Total
High-skilled workers	0.443 [0.427 ; 0.460]	0.359 [0.342 ; 0.376]	0.383
Middle-skilled workers	0.272 [0.258 ; 0.288]	0.342 [0.325 ; 0.359]	0.322
Low-skilled workers	0.284 [0.269 ; 0.300]	0.299 [0.283 ; 0.316]	0.295
Lower secondary or less	0.196 [0.183 ; 0.210]	0.101 [0.090 ; 0.112]	0.128
Upper secondary	0.459 [0.443 ; 0.476]	0.433 [0.416 ; 0.451]	0.441
Tertiary prof or bachelor's degree	0.235 [0.222 ; 0.249]	0.427 [0.410 ; 0.445]	0.372
Tertiary master's degree and more	0.110 [0.100 ; 0.120]	0.039 [0.033 ; 0.046]	0.059
Female	0.485 [0.468 ; 0.502]	0.427 [0.409 ; 0.444]	0.443
Agriculture	0.012 [0.009 ; 0.017]	0.010 [0.007 ; 0.014]	0.011

3.2 From theory to empirics: statistical methods

Our analytical framework is based on a so-called mediation model (VanderWeele, 2016) and follows the (conceptual) Figure 1 presented in section 2. This empirical approach is based on a theoretical framework according to which digital use has direct effects on job satisfaction, but also indirect effects. Digital use is associated with certain work organization practices, which in turn can influence job satisfaction. Thus, we adopt a mediation model that allows distinguishing quantitatively the part of the relationship directly attributable to digital use from that resulting from interactions between digital use and organizational practices (Minardi et al., 2023). The mediation model analysis involves three sets of variables: a predictor variable, a mediator variable, and an outcome variable (Imai et al., 2010; VanderWeele, 2016). The predictor variable is the one that is believed to influence the outcome variable; the mediator variables are the ones that are supposed to be the mechanism through which the predictor variable exerts its influence on the outcome variable; the outcome variable is the one that is being predicted or explained. This approach is strongly dependent on the conceptual framework since it is based on an *ex-ante* structure of relationships. In our case, however, the cross-section nature of our data does not allow us to identify causal mediation analysis.

To conduct a mediation model analysis, we first test for the presence of a direct relationship between the predictor and outcome variables. We then test for the presence of a relationship between the predictor and mediator variables, and between the mediator and outcome variables. The mediation model analysis allows understanding the specific mechanisms through which a predictor variable influences an outcome variable, which can provide insights into the underlying processes at work and inform the interrelationships of social phenomenon.

By reference to Figure 1, our mediation analysis identifies the direct effects (Relation 2.1) of digital use on job satisfaction and then observes the association between digital use and organizational practices (mediation variables: Relation 2.2) and organizational practices on satisfaction (Relation 3.1). Finally, by combining these two latter relations we can identify the indirect effects of digital use on job satisfaction (Relation 2.2 x Relation 3.1). Also, to go deeper into the comparative analysis of digital use between both countries, we first analyze the determinant of digital use (Relation 1.1).

All the results presented are controlled for differences in employees' characteristics, allowing for all other things to be equal analysis. The effects are neutralized for possible relationships arising from the socioeconomic variables presented above. All of these characteristics are likely to affect digital use, organizational practices, and job satisfaction. As some of the employees did not answer all the questions we refer to in the regression, then the sample for the regression is limited to 6,386 (3,281 French and 3,105 Japanese).

We obtain the first set of regression of determinants of digital use and then the second set of mediation analysis regressions on job satisfaction. Then, we extend the second set of mediation analysis by adding interaction terms of digital use to identify some heterogeneity. We carry out multivariate analysis by interacting digital use with under-skilled in digital tools dummy, education level, gender, sector, and occupation. All regressions sets are performed on the full sample, the French and the Japanese sub-samples to identify different patterns.

4 Results

4.1 Determinants and patterns of digital use in Japan and France

As for the determinants and patterns of digital use, there are no major differences between Japan and France, but a little more homogenous pattern in Japan, with some exceptions. There are some signs of a digital divide in both countries from the viewpoint of digital use, especially when one looks at the size of the workplace, the skills, or the education level. This is all the more important that there is a strong correlation between digital use and wages.

In detail, the larger the size of the workplace, the more important is digital use. This relation is particularly true in the case of Japan, where the effect is larger and more significant. In addition, digital use is significantly lower for lower-skilled workers and significantly higher for the higher level of education from the upper secondary level, for both countries, but more in France. There are also differences across sectors with different patterns between France and Japan: digital use is significantly less important in Japanese agriculture as well as in French manufacturing and construction. It is also worth mentioning that being a woman or having a permanent contract in France significantly

increases the probability of digital use, whereas digital use decreases with the age in Japan but not in France. Finally, the correlation between digital use and the index of hourly earnings is significant and strong in both countries but even stronger in Japan (0.558 vs 0.505).

4.2 Analyzing the (direct) impact of digital use on job satisfaction

In table 4, we first confirm that, all other things equal, Japanese workers are less satisfied at work, as shown by the significant unexplained lower level of job satisfaction (-0.060); moreover, it is interesting to note that, when work organization variables are introduced (column 2), the job satisfaction of Japanese workers is even lower by comparison to French workers. It means that differences in work organization practices

between France and Japan reduce the job satisfaction gap: if France and Japan had the same work organization characteristics, the job satisfaction gap between the two countries would be higher. To put it differently, this is because work organization characteristics are different in France and Japan that the job satisfaction gap is smaller.

We now move to the analysis of the direct impact of digital use on job satisfaction (Table 4). For the full sample, we do not find any significant effect of digital use on job satisfaction, which confirms the results of previous studies (Berg-Beckhoff et al., 2017). This is true whatever the specification we consider but it is worth noting that the sign changes (turning negative) when one introduces work organization variables. This is also true in the case of the subsample of Japanese workers. In the case of French workers,

digital use has a positive effect on job satisfaction, which disappears when work organization characteristics are introduced, confirming the relationships between work-organisation practices and digital use.

4.3 Analyzing the impact of digital use on work organization and its indirect impact on job satisfaction

We then move to the analysis of the indirect (mediated) impact of digital use on job satisfaction through work organization variables. We start our investigation by the analysis of the correlation between digital use and work organization variables. In the case of the full sample, we find a positive and significant correlation between digital use on the one hand and three work organization variables: training, autonomy and flexibility, and learning practices but no correlation with cooperation at work.

When one looks at the subsample, we get similar results for France and Japan in the case of training as well as for autonomy and flexibility. However, there are differences between the two other work organization variables. Learning practices are much more significantly positively correlated to digital use in the case of France (0.125) than in the case of Japan (0.035). Moreover, French workers experience higher cooperation at work when they increase their digital use (0.081) unlike Japanese workers (non-significant coefficient).

Given these results regarding the correlation between digital use and work organization, are we able to identify the indirect effects of digital use on job satisfaction through work organization? In the case of the full sample, we indeed find a positive and significant correlation between job satisfaction on the one hand and learning practices, autonomy and flexibility on the other hand. This holds for French and Japanese workers but the coefficients are much higher in the first case. As for training and cooperation, we find some substantial differences between France and Japan. As for training practices, it is not correlated with job satisfaction in the Japanese case but it is associated with a lower level of job satisfaction in the French case. Even more interestingly, if we remember the results of the first step (positive correlation between digital use and cooperation for French workers but not for Japanese workers), we find a positive correlation between cooperation and job satisfaction in Japan but not in France.

To summarize (Figure 3), while there is no direct relation between digital use on job satisfaction, there are indirect impacts, through work organizations, in a similar way for France and Japan for autonomy and flexibility, which is positive. As for other work organization characteristics (learning and training), the patterns are different between the two countries. If these two practices are more frequent for workers, who are exposed to digital use, training tends to be associated with a lower level of job satisfaction conversely to learning practices which is related to better satisfaction.

4.4 Which digital divide in France and Japan from the perspective of job satisfaction?

The existence of a digital divide during the process of digitalization has attracted a lot of attention from the perspectives of infrastructure, usage, and income. Here, we investigate the existence of this digital divide from the perspective of job satisfaction by comparing French and Japanese patterns of interactions with several individual characteristics such as skills in digital use, gender, education level, occupation, sectors and type of contract (Table 6). Without surprise, the most massive source of the digital divide is, in both countries (but again with a stronger effect for France), related to the absence of (subjective) appropriate digital skills: digital use significantly increases job satisfaction for those who consider that they have the digital skills, whereas it decreases it for the others.

As for the other sources of individual heterogeneity, the patterns are different between the two countries. In the case of Japan, the digital divide by education level is the most important, while it is not significant in the French case. Except for highly-educated workers, for which digital use does not lead to higher satisfaction, having a higher level of education leads to a positive impact of digital use on job satisfaction. As for France, and contrary to Japan, sectoral differences matter in the emergence of a digital divide: job satisfaction is increased by digital use in the agricultural and manufacturing sectors and decreased in the transport sector. Similarly, digital use slightly increases job satisfaction for high-skilled French workers (defined by occupation) but not for Japanese workers.

Finally, surprisingly, we do not find any significant effect of the type of contract (open-ended vs. short-term contract) on satisfaction in itself (Figure 1A) but also no effect in the case of interaction with digital use (Table 6). Previous work in the European context stressed that stability and career prospects are related to job satisfaction (Clark, 2015; Eurofound, 2017a; Bustillo et al., 2011). Nevertheless, the type of contract (open-ended vs. short-term contract) is not strongly linked to stability and career prospects. In other words, the perception of stability and prospects is not determined by the fact that the worker is on an open-ended contract. In the Japanese case, some previous works underlined the positive relationship between job satisfaction and regular jobs (Matsuki and Nakamura, 2018); however, the type of contract does not reflect the regular or non-regular employment statute of the worker (Kambayashi and Kato, 2016). For these

reasons, we can assume that our variable of the type of contract is not enough sufficient to measure job stability and career prospects and can explain the absence of relationships.

These results, which take into account within countries differences (among workers with different characteristics), relativize the similarity of patterns in Japan and France that were found previously. It should lead us to more systematically and jointly investigate the within and between-countries differences to better understand the indirect impact of digital use on job satisfaction that goes through work organization variables.

4.5 Limitations and robustness of the analysis

Our results face several limitations, which have to be stressed. First, as presented above the cross-sectional dimension of our data is a limit that does not allow one to identify causal relationships. We establish only correlation and association, even if our statistical technics allow us to clarify the relations and the many variables used to avoid several confounding issues. Nevertheless, some aspects can be viewed as more robust than others. The theoretical framework presented in section 2 as well as the literature can help to first assess the robustness of some results. The reverse causality issue is present mainly in the relationship between work-organisation practices and digital use (Relation 2.2). The findings from the literature remain inconclusive since some works support that work organization can determine technology production and adoption, while others support

rather the primacy of technology adoption as a shock at the workplace that implies to adapt work-organisation. Finally, some other works argue that technology adoption and work organisation are codetermined. Beyond the structure of the data, the conceptual framework is itself a limitation. On the contrary, the other relationships are more clear-cut. Because Relation 1.1 is focused on the structural (socio-economic and contextual) determinants of digital use, it is difficult to support reverse causality. Similarly, it seems also difficult to argue that job satisfaction could determine digital use or work organization practices, or if it plays a role it would be a very limited one. For these reasons we can first assert the conceptual framework that allows us to provide insights into the technology-working conditions relationships.

Nevertheless, to assess the robustness of our results, we also conducted a set of statistical tests. The variables used are index-transformation of the initial ordinal variable, and even though it appears more relevant to keep most of the variance some studies prefer to use dummified variables. The main reason is that the interpretation can be clearer mainly in terms of the presentation of the results. A good assessment is to find relatively similar results regardless of the data processing used. Divergent results would support the fact that the distribution of the initial variable can be very particular. Without surprise, the results with dummy variables (for digital use, job satisfaction and work organization) give very similar results, but these results slightly vary in terms of significance according to the threshold used for processing ordinal variables to binary variables. This latter aspect supports our argument of index processing to keep all the variance and avoid the arbitrary threshold for dummification.

To deal with the codetermination issue, we have tried to instrument the digital use variable. To do so, the abundance of variables in PIAAC data is a real advantage, but unfortunately, no good instrument was found. A good instrument must be relevant, have good predictive power, be precise, exogenous (from other confounding variables but also the instrumented variable), and independent (from the outcome variables). We try two strategies of instrumentation, one with the measured skill in literacy and numeracy in PIAAC and one with several (relatively) exogeneous and time-invariant socio-economic variables (age, gender, education level, family structure). For both strategies the predictive power was not sufficiently good but even more problematic, the instruments

are not independent of the outcome variables (work organization practices as well as job satisfaction).

5 Discussion and concluding remarks

In this paper, we have analyzed the diverse impacts of digital use on job quality by comparing work organization and job satisfaction in Japan and France. Digitalization has indeed attracted a lot of attention with a focus on its impact on performance (labour productivity) and volume effects (job creation/destruction). More qualitative dimensions of the impact of digital use on work and labour have been relatively neglected, while the discussion on the digital divide has not dealt at all with the quality of job issues but rather infrastructure and use issues. Therefore, we try to fill the gap by focusing on a comparison between two OECD countries, which are supposed to be different in terms of digitalization (Japan being considered a laggard) and job satisfaction and work organization. We may thus assume that the impact of digitalization will be different between the two countries.

A major difficulty in this investigation is that there is no unified model linking digital use and job quality. The challenge is to study several simultaneous relations, at different levels of analysis, and with direct and indirect effects (mediation factors). To be able to test the relationships between digital use and job quality we introduce a simplified mediation model that synthesizes the different relations of interest.

Based on the PIAAC 2013 Survey, our results can be summarized as follows. First, surprisingly, despite differences in work organization and job satisfaction between France and Japan, we did not find overall substantial differences between the two countries regarding the impact of digital use on job quality.

Second, in more detail, there are differences between French and Japanese workers in the mechanisms at work but the overall outcome is similar. In general, we find no direct effect of digital use on job satisfaction. However, digital use is associated with work organization forms (mainly autonomy and flexibility; learning), through which it has positive indirect effects on job satisfaction.

Third, the absence of direct effects of digital use on job satisfaction can be decomposed into a negative effect of digital use (techno-strain) compensated by a positive

effect for those who have the right digital skills. This mechanism is a source of inequalities within each country. To put it differently, the most massive source of the digital divide is, in both countries, related to the absence of digital skills.

Moreover, our fourth major result suggests there are also other sources of individual heterogeneity, for which the patterns are different between the two countries. In the case of Japan, another digital divide appears by education level and it is only slightly correlated with the existence of digital skills. In the case of France, the other sources of the digital divide are related to the differences across sectors and also, in a less important way, across occupations.

It means that the similar patterns between Japan and France that have been found in our initial model are relativized when one looks at within countries differences (among workers with different characteristics). It should lead us to more systematically and jointly investigate the within and between countries differences regarding the impact of digital use on job quality.

Finally, it is worth mentioning some of the limitations of our paper, which can be a starting point for further investigation. Here, we limit ourselves to two major ones. First, while the comparison between Japan and France is of interest because of the differences between the two countries, it is difficult to assume that it allows us to describe a general pattern that could be observed as well in other countries. It is thus necessary to extend the international comparison to have a better understanding of the impact of digital use on job quality. Second, as the data used in this paper are relatively old, our contribution can be considered as rather a historical investigation of the impact of the first wave of the introduction of digital technologies in the workplace. It means that other investigations are required to analyze this relationship in the most recent period. In particular, it would be interesting to analyze whether the converging differences that we have found between Japan and France have changed over the most recent period, especially in the context of the spread of telework.

Appendix

Table A1: List of the created variables

Created variables	Variables used in PIAAC	Methods	Type of the variable
Index of ICT use	Frequency use of internet at work - email (g_q05a) Frequency use of internet at work - better understand issues related to work (g_q05c) Frequency use at work - spreadsheet software (g_q05e) Frequency use at work - word processor (g_q05f)	(1) All the ordinal variables are standardized from 0 (lowest category) to 1 (highest category) (2) Correlations (PCA, pearson correlation, alpha's Cronbach) are validated (3) Index is created by a mean all the standardized variables	Continuous variable (0 to 1)
Index of satisfaction	Satisfaction level with the current job (d_q14)	(1) The ordinal variable is standardized from 0 (lowest category) to 1 (highest category)	Continuous variable (0 to 1)
Autonomy and flexibility index	Control over pace of work (d_q11a) Control over work methods (d_q11b) Control over speed of work (d_q11c) Control over working hours (d_q11d)	(1) All the ordinal variables are standardized from 0 (lowest category) to 1 (highest category) (2) Correlations (PCA, pearson correlation, alpha's Cronbach) are validated (3) Index is created by a mean all the standardized variables	Continuous variable (0 to 1)
Planning your own activities (score)	Planning your own activities (f_q03a)	(1) The ordinal variable is standardized from 0 (lowest category) to 1 (highest category)	Continuous variable (0 to 1)

Learning index (score)	Learning from co-workers (d_q13b) Learning-by-doing (d_q13c)	(1) All the ordinal variable are standardized from 0 (lowest category) to 1 (highest category) (2) Correlations (PCA, pearson correlation, alpha's Cronbach) are validated (3) Index is created by a mean all the standardized variables	Continuous variable (0 to 1)
Cooperation index (score)	Sharing information with co-workers (f_q02a) Time cooperating with co-workers (f_q01b)	(1) All the ordinal variables are standardized from 0 (lowest category) to 1 (highest category) (2) Correlations (PCA, pearson correlation, alpha's Cronbach) are validated (3) Index is created by a mean all the standardized variables	Continuous variable (0 to 1)
Participated in formal or non-formal training (dummy)	Participated in formal or non-formal training (fnfaet12)	(1) A dummy variable is created for employees who benefited a training	Dummy variable
Hourly net wage index	Hourly net wage with bonuses - parity purchase power (in \$) (earnmthbonusppp)	(1) The hourly net wage is converted in logarithme to normalize the distribution (2) A standardized index is created with 1 as the highest value and 0 the lowest one	Continuous variable (0 to 1)

Figure 1A: Direct relations of digital use and work organisations practices on job satisfaction in France and Japan (*Relation 2.1 and Relation 3.1*) – full regression

Source: PIAAC data – 2011. French (4,095) and Japan (3,717) employees. Regression analysis (OLS) on the index of digital use. Marginal effects reported, with confidence intervals (95%). *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$, + $p < 0.1$.
